The committee suggest that the regulation should be altered so that "the first of the five years of the curriculum may be spent in obtaining instruction in chemistry, physics, practical chemistry, and biology, either at a recognised institution or at a recognised medical school, and that the candidate be required to spend four winter and four summer sessions from the date of passing Parts I. and III. of the first examination at a recognised medical school and hospital before entrance to the examinations in medicine and surgery. In relation to this suggestion the committee would remind the Royal Colleges that great care has been taken in selecting the institutions placed on the recognised list, some being recognised for chemistry, physics, and practical chemistry only and others for biology as well. In the case of students attending the former class of institution the committee propose that not more than six months of the curriculum shall be allowed to count, but in those cases where biology is also taught the full period of a year should be recognised."

Dr. NORMAN MOORE pointed out that a similar practice was in vogue at the Universities of Edinburgh, Glasgow, and St. Andrews, whilst the University of London did not require of candidates for the preliminary scientific examination that they should study at any recognised institution, and that having passed that examination they could take the medical degree after four years' study in a medical school. The motion was seconded by the Senior Censor.

Dr. PAYNE pointed out the importance of the question, which amounted to granting permission for the first year of "medical study" to be passed at school. He did not mean to say that it should be obligatory on the student to receive his instruction in these subjects at a medical school, but he deprecated the inclusion in institutions for this "first year of professional study" of places such as technical schools and higher grade board schools, which although recognised as science schools by the Science and Art Department of South Kensington could hardly be regarded as places of liberal education suitable for the preliminary studies which gave entrance to the medical profession. He would move that institutions of the class he had referred to be excluded from the proposed recognition as places of professional study.

The REGISTRAR said that the committee's recommendation was quite in accordance with the regulations of the General Medical Council. He would be very sorry to see the chances for distinction being removed from scholars of technical and higher grade schools and mentioned an instance where one whose career commenced at such a school had graduated in medicine at the London University and obtained the Membership of the College.

Dr. NORMAN MOORE, in reply to Dr. Payne's criticisms, said that no institution was recognised until it had been thoroughly investigated and he claimed that many of the schools in question were far better equipped in laboratories than most medical schools. The medical schools had been consulted upon the desirability of the proposed change and had practically concurred in it.

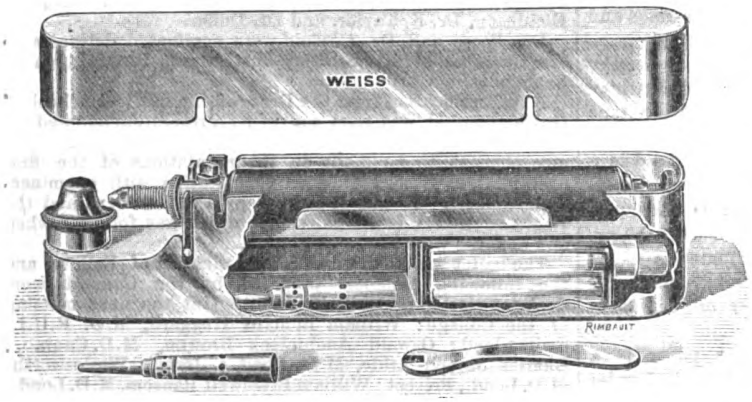
On the motion of Dr. CHURCH, seconded by Dr. LEE, the debate was adjourned to the next meeting of the College.

New Inventions.

THE DÉCHERY AUTOMATIC CAUTERY.

THIS apparatus resembles other cauteries only in that it utilises the incandescent properties of platinum. The bellows and benzoline reservoir of the ordinary thermo-cautery are rendered unnecessary, as the instrument works automatically, a minute stream of ether, projected into the previously heated platinum knife or point, supporting incandescence, which may be sustained for a period of from thirty to forty minutes, the consumption of ether meanwhile being only half an ounce. The cautery should be absolutely safe in use, being made throughout of metal, with an insulating cover to protect the operator's hand from heat, and in manufacture, we are informed, each instrument is tested by being subjected to an internal pressure equal to ten atmospheres, that occurring in actual use not exceeding three.

FIG. 1.



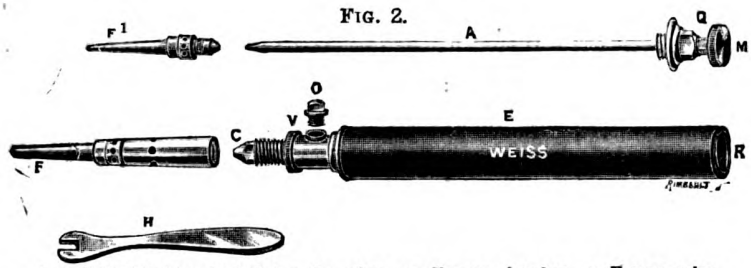


FIG. 2.

R E, Cylindrical handle holding the ether. V, Vapour chamber. C, Escape valve. F, F1, Platinum knife and point. H, Steel key. A, Metallic rod traversing handle, with M, regulating screw, &c.

FIG. 3.

The apparatus as submitted to us is very portable, being contained in a metal case 10 in. by 1½ in. by 2 in. deep.

To use the cautery the screw-stopper marked O is removed by means of the key H and the reservoir is filled with ether or a mixture of ether and alcohol, an ether bottle with a curved nozzle being supplied with the instrument. The stopper must be firmly replaced. The milled head M being firmly screwed home, the instrument is held with the point obliquely downwards and that part containing the vapour chamber V is placed in the flame of a spirit lamp for about two minutes (or less—according to the season), when small flames will be observed to issue from the air-holes below the platinum part. The valve is opened by slightly turning the milled head M to the left, the point being held in the flame until a sound of rushing air is heard. Should any flame now remain it may be blown out and the instrument should be reversed a few times in order to equally distribute the heat internally. It may at this stage be necessary to again heat the vapour chamber portion. By manipulation of the regulating screw M the desired degree of heat at the point may now be sustained. Following the above directions we have tested the Déchery Automatic Cautery and consider it a valuable instrument, being strong, neat, and portable, while its use certainly minimises the risk of accidents. The inclusive price of the apparatus is £5 5s. and the makers are Messrs. John Weiss and Son, 287, Oxford-street, W.

THE LANCET.

LONDON: SATURDAY, MAY 7, 1898.

PUBLIC honour is but rarely done to the medical profession, so that it is with particular pleasure that we record the fact that the dinner given by Colonel H. D. DAVIES, M.P., the Lord Mayor of London, "to meet the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, and other members of the medical profession," was an unqualified success. The dinner was carried out in the true spirit of great civic hospitality, wherefore all the guests were happy as well as honoured, a conjugation of events by no means necessarily present in all semi-public functions, although a conjugation which may be looked forward to with certainty when the host is the Lord Mayor of London. We desire to congratulate his Lordship and his able secretary, Mr. W. J. SOULSBY, C.B., on having given to a representative assembly of medical men a very pleasant evening; while on the wise and graceful sentiments that prompted his Lordship thus publicly to honour the Presidents of the two Royal Colleges, of which so large a proportion of English medical men are diplomates, we must say more than a few words of perfunctory praise.

We members of the profession of medicine stand at the present moment in need of conspicuous support. In all directions our calling has enlarged its boundaries and in all directions it is seeking further to enlarge them. Take one example only. The medical work of the Local Government Board, enormous as it is, is the growth of comparatively few years and assuredly will develop at an even greater rate than it has hitherto developed. But this sturdiness of growth, this irresistible tendency to annexation, has not been, and will not be, regarded complacently by all. Every extension of the work of State medicine means an invasion of provinces where private or, at any rate, non-sanitary interests have previously been paramount. Therefore every extension is and must be regarded by a certain section of the population as an act of raiding and as a consequence provokes a spirit of opposition to those entrusted with the duty of carrying it out. The bitter and unworthy comments which certain of our lay contemporaries do not hesitate to make, and to make with wearisome reiteration, concerning the profession of medicine is the outward expression of this spirit of opposition; and although a wise majority of our fellow citizens can detect in the strictures of those whose policy is always to be "agin the doctor" an ignorance that should detract wholly from the force of the criticisms, yet it undoubtedly does harm to the profession as a whole that it should be perpetually reviled. A dinner such as that given by Colonel DAVIES on Wednesday evening is therefore particularly opportune. The leaders of commerce do not take much upon trust, for if they did they would not long remain leaders of commerce. Looking upon the Lord Mayor of London—in virtue of his office as the Chief Magistrate of the largest city that the world has ever known—as the type and figure-head of honourable and shrewd business achievement we may regard his public desire to honour our profession as a proof that we enjoy the confidence of commercial England, and that while they recognise in this or that great man a discoverer, an operator, a writer, or a thinker whom they may single out by name for particular respect, they recognise also in the medical profession as a whole a body of men who do arduous work of a value to the nation which cannot be commercially estimated and much of which is not in the least adequately rewarded from a business point of view. Colonel DAVIES'S splendid compliment to the President of the Royal College of Physicians of London and the President of the Royal College of Surgeons of England constitutes a pledge of the trust which is reposed in the medical profession by responsible citizens.

It is nearly seventeen years since the medical profession received the hospitality of the Mansion House. The occasion then was the dinner given by Sir WILLIAM MCARTHUR to 300 members of the Seventh International Medical Congress which met in London in 1881 under the presidency of Sir JAMES PAGET. The guests on that occasion included such world-wide celebrities as PASTEUR, VON LANGENBECK, DONDERS, KLEBS, CORNIL, CHARCOT, ESMARCH, BILLINGS, BIGELOW, BROWN-SÉQUARD, and TARNIER—to mention a few of the names which crowd in on our memory and which, alas, in several instances, bring with them feelings of respectful regret that death has set a limit to their owners' achievements. Colonel DAVIES may not have been able to secure at his board a company quite so brilliantly representative of the highest flights of medical science as were the guests of the late Sir WILLIAM MCARTHUR, for there was no international collection of talent upon which to draw; but the assembly of last Wednesday night was one of which the medical profession may justly feel proud, comprising as it did many men the value of whose services to the State cannot be priced. And for another reason, apart from the facts that this was the first public dinner ever given by a Lord Mayor to MEDICINE and that the guests were so truly representative of medicine in all its many sides, the dinner of May 4th will be a memorable one. For, as will be seen in another column, the Marquis of LANSDOWNE, the Secretary of State for War, made of his speech, in reply to the usual complimentary toast "The Army," an occasion to formulate the concessions which his department are prepared to make to the Army Medical Staff. The Lord Mayor's dinner will, indeed, be a feast of great and fortunate outcome if the words spoken at it by Lord LANSDOWNE should prove, as to our thinking they must prove, the exposition of a scheme for the immediate and practical redress of the grievances of the Army Medical Staff.

THE question of the teaching of the preliminary sciences to intending medical students during their school curriculum is once more under discussion at the Royal College

of Physicians of London, and it is one that cannot be easily settled without acting unequally on various classes of pupils. If a student leaves all his science subjects until he enters a medical school and is then registered as a medical student he has a five years' curriculum before him, and the various stages in his career are laid down with precision and exactness by the examining bodies. In such cases the courses must be taken in the same order practically for the licences of the corporations as for a university degree, although the examinations may differ in severity. In other cases the pupil may be at a school of a first-class grade, where he can be taught the medical preliminary sciences—chemistry, physics, and biology—as thoroughly as at a medical school. He will have efficient masters and completely equipped laboratories, and can be instructed under a more stringent routine and with less distraction than in a medical school. There are many such science schools where these three subjects are taught thoroughly and they are recognised by the authorities of the Conjoint Examining Board in England. The pupils in these schools are registered as medical students and the year's work in these sciences reckons as the first year of the medical curriculum. We understand that all the schools of science in which the three preliminary sciences of chemistry, physics, and biology are now taught register their science pupils as medical students.

But in addition to the schools in which the whole of the scientific curriculum preliminary to a medical career is taught there are a number and a far larger number in which the teaching of chemistry and physics only are recognised by the Conjoint Examining Board. It is obvious that many schools and institutions can give efficient teaching in chemistry and physics, whilst proper instruction with demonstrations of laboratory work in biology would be impossible. Those students, however, who have been instructed in chemistry and physics only—or perhaps but one of these subjects—before entering at a medical school are also registrable as medical students under varying conditions and the work which they may have done at school will relieve them from the full period of a five years' curriculum provided such work has been done at one of the schools or institutions recognised by the authorities of the Conjoint Examining Board and that they have passed the necessary examinations in chemistry and physics. Both the Royal College of Physicians of London and the Royal College of Surgeons of England are evidently very anxious to assist science teaching in schools and consequently are recognising more and more science schools and scientific institutions in all parts of England. During 1897 students were registered not only from university colleges and medical schools but from public schools, grammar schools, schools of science, scientific institutions, and even from polytechnic classes and technical colleges. Such a system introduces much confusion in the first year's teaching at the medical schools and makes the exact status of the individual student a very perplexing question for the medical school authorities as well as for all parents and tutors. A compulsory four years' curriculum after the student had passed these preliminary sciences would be a clearer and better solution of the difficulty than the regulations which are now in force.

ON the fifth day of her trial at the Central Criminal Court CAMILLA NICHOLLS was on May 2nd convicted of the manslaughter of her servant EMILY JANE POPEJOY by prolonged ill-treatment and starvation and sentenced to seven years' penal servitude. Some fourteen months prior to her death the deceased entered the service of Mrs. NICHOLLS at Pitt-street, Kensington; she was then, according to the evidence of several witnesses, well nourished and apparently healthy. At the end of that time she was sent home in a dying condition and within a few days passed away. An inquest was held and a post-mortem examination was made by two medical men. At the necropsy it was found that the body was extremely emaciated, while the lungs were affected by chronic tuberculous disease, to which was added pneumonia of about ten days' standing. The wasting was considered by Mr. H. B. OSBURN and Mr. CREASY to be greater than would be accounted for by the disease and could only be explained by "long and constant withholding of food." It must be conceded that such an opinion carrying as it ought such weighty consequences would only be formed and expressed after a searching examination and the most careful consideration. It is certain that Mrs. NICHOLLS was responsible for supplying the deceased with food of proper quality and in sufficient quantity and it remained to be proved whether she had failed in her statutory duty. There was evidence forthcoming from several sources that she had for a long period deprived the girl of proper nourishment. To habitual under-feeding was added further neglect as a punitive measure. Not only was there direct testimony to this effect but it was proved that deceased on more than one occasion was seen to pick up crusts in the street and eat them. Moreover, she spoke of abiding hunger to a witness who supplied her with food. It will naturally be asked why she did not complain to her parents. To this the reply is that her mistress forbade her writing home except at her dictation and then the facts were falsified. In his summing up Mr. Justice PHILLIMORE directed the jury that the one issue for them to determine was whether the deceased had the means of escaping from her distressing circumstances. They answered that she had not. Whether this was from the direct and overpowering influence of Mrs. NICHOLLS alone or partly from fear of punishment at home for leaving her situation is not clear. To the omission of her duty the prisoner was proved to have added a serious aggravation in that she not only held the girl in thraldom and terror, but treated her repeatedly with physical violence, on one occasion breaking her nose and on another striking her foot with a hammer. A strenuous attempt was made by counsel for the defence to show that the prosecution had failed to prove that death was not due to natural causes and that the evidence of more than one witness as to cruelty—and notably that of a fellow servant—was unworthy of credence. As regards the latter, whilst allowing a wide margin in favour of the prisoner, it was impossible for the jury to assume that one and all were wilfully forswearing

themselves. There was far too much consistent corroborative testimony to warrant such a conclusion.

The medico-legal aspects of the case are most engrossing. The Society for the Prevention of Cruelty to Children could tell of the extreme difficulty which they have experienced in establishing charges of starvation, and investigations held on coroners' inquisitions confirm the same. The difficulty is rendered greater and sometimes insuperable in cases where grave organic disease—and notably tuberculosis—exists, whether diagnosed during life or discovered after death. Starvation and disease act reciprocally and intensify each the other, so that the utmost care in observation and discretion in forming an opinion are required and the obligation becomes paramount where the life or liberty of a fellow being is at stake. Without challenging the conclusions of the medical men who made the post-mortem examination we may acknowledge the gravity and extreme complexity of their task. *Primâ facie* we should have inclined to the view that even pronounced general wasting might be explained by advanced tuberculous disease of the lungs and that death might follow as a consequence of such disease supplemented by recent pneumonia. The nature and degree of the chronic pathological process can be duly appreciated only by those who have the facts under direct observation; mere academic opinion of those facts as reported by others is very properly received with philosophic doubt. Counsel for the defence must have felt their powers of advocacy severely tasked to nullify the proposition of the prosecution that the lung disease was insufficient to explain the emaciation and to combat the non-professional testimony as to the frequent appearance of bruises on the body of JANE POPEJOY. Diabetes was advanced as possibly existing—a disorder capable at once of answering for general emaciation, and of substituting purpuric patches for hæmorrhages caused by external violence; but there were no convincing facts that the deceased suffered from this malady.

Whilst strongly protesting against the popular indignation expressed whilst the convict was awaiting her trial, we feel constrained to subscribe to the finding of the jury. Much of the evidence was certainly open to suspicion and many statements were probably exaggerated if not demonstrably contrary to fact, yet an impartial consideration could not well have led to any other conclusion than that NICHOLLS through criminal omission of duty and commission of illegal acts was justly convicted of having contributed to the death of the unfortunate girl. She must have noticed the gradual wasting and failing strength of her servant and yet not until within a few days of her death did she take any steps to acquaint the parents with the serious condition of their child.

IF we are not of the number of those who see no urgency in the need for measures to protect poor lying-in women from the risks of being attended by ignorant and untrained midwives we are none the less of opinion that the present Bill before Parliament is not one which is likely to diminish such risks. These risks are so obvious and have been so often illustrated in our columns and at coroners' inquests that we should think ourselves blameworthy not to recognise them and to approve means for their mitigation. If all modern teaching on the origin of puerperal fever is not a delusion that disease must be fostered on a large scale by dirtiness and ignorance in a midwife. Parturition may be "a natural process," but if so it is the only natural function that we know of which is attended with much pain and suffering and, we might add, liability to be followed by very unnatural processes of disease, including the risk of permanent injury and even death. But this only makes it the more desirable to act with caution and to preserve the practice of midwifery as an essential part of the art and science of medicine.

The recent discussion of the question in the General Medical Council and an admirable letter by Mrs. GARRETT ANDERSON in the *Times* of April 30th have tended much to clarify the subject and to define what is really wanted and what is not wanted in any legislation. Mrs. GARRETT ANDERSON points out in her letter that the Bill now before Parliament seems more calculated to improve the status of midwives and to raise them into a semi-medical position than to benefit the parturient poor. We trust we shall not be considered uncharitable if we say that this Bill is mainly meant by its promoters to improve the status of the midwife. It is promoted by the Midwives' Institute and this particular object is admitted by the promoters. There can be no objection to any reasonable improvement in the status of midwives; but that is certainly not the object of the public in upholding the movement. The object of the public and of the medical profession is the protection of lying-in women. So far as an improvement in the status of midwives is necessary to advance this object so far will it be conceded. But the contention of those who have studied the question deeply is that the Bill will advance the status of some midwives while leaving the poor parturient woman still in the hands of the ignorant midwife. It will do so in two ways. It will place on the midwives' register thousands of women who are untrained and unfit and give them a new lease of life and a rise in status, and in its present form it will give to all midwives a status which they have not at present and on the strength of which it will be easy for them to assume medical functions with great disaster to the public interest. Mrs. GARRETT ANDERSON makes these points very clear. She shows that without precautions which have not been taken in this Bill the midwife to be created by it will soon develop into a practitioner who will despise practice among the classes for whose benefit the Bill is designed and will aim wholly at competing for the midwifery practice of the medical profession. It is a notorious fact that the improvement in midwifery practice dates from the time when it largely ceased to be carried on by midwives and came to be regarded as a very serious and onerous part of medical work. The Medical Act of 1886 very properly recognised this great and beneficent change and placed the practice of midwifery on a level with that of medicine and surgery. If a Midwives Bill is to create a pretentious class of practitioners in midwifery it will tend to degrade the art of midwifery and to defeat the ends of the Act of 1886. Medical men

can only guide the art of midwifery to greater perfection and efficiency by still having the bulk of it in their hands. They cannot be responsible for the difficulties arising in midwifery practice if deprived of the practice; hence it is essential in any legislation on the subject of midwives to emphasise the fact that midwives are to have no strictly medical functions and that in all unnatural or unusual conditions they are to apply and appeal to the medical professional for assistance or advice. Any Bill which imperils the position of midwifery as a part of the great art of medicine and weakens the Act of 1886 is no friend of poor lying-in women, a view which the General Medical Council have taken in their response to the invitation of the Privy Council for advice.

We cannot doubt that the House of Commons will see the gravity of the question with which it is asked to deal and the inadequacy of the Bill which it is asked to pass. In addition to the considerations which we have already advanced and which are enough to justify the rejection of the Bill there is another more convincing still. The Bill proposes only to render illegal the assumption of the title of midwife. It leaves any woman who likes to do so to discharge the duties and to carry on the practice of a midwife. Amongst the poor a title does not need to be assumed; it is given. A woman need only give herself out as ready to do the duty of a midwife and her neighbours will give her the duty and the title too. And the same mortality and morbidity as at present will go on. If the intention of Parliament is to stop these evils and to make the lives of women safer it must stop the practice of ignorant and untrained women altogether and place that of the future midwife, with a modest training, strictly under the effective supervision of the medical profession. We look confidently to Parliament to do this service, and after the speech of the Lord President of the Council to a deputation in favour of the Bill on Monday last which was marked by the speaker's usual practical wisdom, we may reasonably hope that Parliament will take our view. The Duke of DEVONSHIRE advised the promoters of the Bill to come to terms with the General Medical Council and with the medical profession rather than to press the existing Bill forward. He did not think that he could advise the Government to support the Bill against the medical profession. In addition to their objections he had received a memorandum from the Local Government Board suggesting difficulties in the form of protests from the local sanitary authorities upon whom and whose officers serious and costly duties were laid by the Bill. This objection may be overcome and should be overcome if an effective and acceptable Bill can be devised grappling with the great evils of a class of ignorant and untrained midwives. But the present is not such a measure.

IT was a happy thought o the Marquis of LANSDOWNE to select the unique occasion of a dinner at the Mansion House in honour of the medical profession to narrate the plans of the War Office for redressing the present grievances of the Army Medical Officers. In no way could the Secretary of State for War have more entirely coöperated with the Lord Mayor in giving a public voice to the high estimate in which members of our profession are held by their fellow citizens than by choosing his seat at the Lord Mayor's table from which to deliver his ringing words in approbation of the services rendered by the Army Medical Staff and the desire of his Department to remove all causes of disagreement between the army and the medical officers of the army. "The army is proud," said Lord LANSDOWNE, "that it contains a number of officers who belong to the medical profession, but who are none the less soldiers in the fullest sense of the word, wearing the QUEEN'S uniform, holding her commission, ready to take their share—aye, and more than their share—of the risks and hardships of warfare. We are determined that there shall be no failure, either in theory or in practice, to treat them with the respect to which they are entitled." Following these words of promise his lordship said that the Army Medical Staff and the Medical Staff Corps would be consolidated into a corps with the same military titles as other officers of the army up to the rank of "Colonel"—the titles of course not conferring any right of command outside the corps; and that HER MAJESTY THE QUEEN had signified her intention of bestowing upon the newly formed corps the title of the Royal Army Medical Corps. This clear statement seems to us to redeem the happy promise. An officer in such a Royal corps called by a familiar military title and enjoying within his corps the position of other officers in the army of his own rank can no longer be regarded, or suspect that he is regarded, as other than an integral part of the army, for his military and medical status are alike defined and certain. There is here no question of relative rank or of substantive rank whatever. He will enjoy actual rank. The fact that the title of "General" will not be granted save in the compound expression of "Surgeon-General" appears to us to be a reasonable reservation in view of Lord LANSDOWNE'S declaration that the present policy of the War Office is to restrict the number of officers bearing the title of General to those officers who may be required to fill one of a limited number of appointments, all of which will involve general command in the army and fitness to command troops in the field. Under such a restriction no departmental officer will be able to reach the rank of general officer. But surely the title of Surgeon-General is an honourable and well-sounding appellation, conveying the high rank, both military and special, which is held by its bearer. We congratulate the Army Medical Staff on the successful issue of their claims for redress. With a definite military status the service should again become popular, while with the gaps in its ranks adequately filled other grievances—for example, the difficulty of obtaining leave and facilities for pursuing scientific investigation — must disappear. Finally, to Lord LANSDOWNE the whole profession owes a debt for his outspoken words in appreciation of the medical men of the army. It was impossible to hear them, and we know that it will be impossible to read these words, without feeling that they must exercise a vast influence for good in serving to heal the breach of many years.

Annotations.

"Ne quid nimis."

EXEMPTION OF CROWN PROPERTY FROM SANITARY CONTROL.

THE exclusion of the agents of the local authority from all buildings, premises, and vessels belonging to or used for the time by the Government, and the exemption of such property from the provisions of the Public Health and kindred Acts, though recognised as a part of the prerogative of the Sovereign, must be considered an anachronism. It is, indeed, necessary in the interests of the nation that the Crown should possess powers of an arbitrary character and occasionally acting hardly on individuals, as that of appropriating patents, which is, however, rarely exercised save in respect of the appliances of war and national defence, and that the persons of members of the diplomatic service should be held sacred. But we are unable to conceive on what pretext of expediency the exemption of post-offices and police-stations from provisions enjoined or approved by the central authority for the preservation of the public health and the prevention of loss of life by fire can be pleaded. It is not long since the person in charge of a house used as a branch post-office in the E.C. district was severely reprimanded by his superiors for having admitted the sanitary inspector, and the intimation and statutory notices served by the local authority for the abatement of the nuisance—i.e., the removal of serious sanitary defects endangering the health of the inmates of the house and probably of those adjoining—having been ignored the vestry applied for a summons. The magistrate in declining to grant it expressed his great regret and, in no hesitating manner, his disapproval of a law or custom under which grave abuses could be permitted. Since the great fire in Cripplegate the local authorities and the Building and Licensing Committees of the London County Council have been redoubling their exertions, not infrequently requiring the reconstruction of arrangements for escape which they had previously sanctioned, and putting some City firms to expenses amounting to £2000 or £3000. Yet we are told by those who ought to know best that the sole means of entrance to and exit from the principal room at the Central Telegraph Office is a winding stair-case, only wide enough for two persons, by which at 8 P.M. 900 men pass out and 250 in, the crush being indescribable. We fear the consequences of a fire as sudden as that in Hamsell-street or even of a mere alarm would not, like those of the Cripplegate disaster, be confined to loss of property. Again, while the medical attendant in an ordinary case is bound under a penalty to notify all cases of infectious disease he may be called to see, and the patients or persons in charge are bound to avoid exposure or other means of spreading the infection, in the case of a Government building there is nothing to prevent the concealment of cases of small-pox or diphtheria and the establishment of centres of diffusion in the families of the resident staff at such places as post-offices, police-stations, or, for the matter of that, in the offices of the Local Government Board itself. All the other privileges are based on unwritten custom and precedent, the exemption from notification alone being statutory. We are, however, informed that one of Her Majesty's Secretaries of State has relaxed the prohibition, temporarily and as a matter of favour, not of right.

THE SPEAKER ON HOSPITAL WORK.

THE Speaker has been kindly presiding at a dinner held in aid of the Building Fund of the Royal Westminster Ophthalmic Hospital, Charing-cross, and was worthily surrounded by honourable Members of the House over which he so ably presides. Between the Speaker's eloquence and what he called the eloquence of the figures of the growth of the number of patients using the hospital the result was considerable. A subscription of over £2000 was raised, of which more than £1500 was on the chairman's list. In the last fourteen years there had been an increase of 126 per cent. in the patients. The out-patients had increased from 4954 in 1850 to 10,588 in 1897. £50 000 were asked for, one-fifth of which would probably be required for the site in the neighbourhood of Charing-cross and the rest for building and endowment. The great increase of knowledge in recent years in regard to the treatment of special diseases necessitated new appliances, new remedies, and larger space. Mr. Cowell, the treasurer, in responding for the executive staff, alluded to some of the causes of the great difficulty which hospitals had in obtaining the money they required, and especially mentioned the unchecked multiplication of small hospitals which added greatly to the total amount spent on administration and to the diminution in the receipts of many of the smaller hospitals caused by the establishment of the Prince of Wales's Fund. He did not wish in the least to disparage that fund, but he could not help saying that in his opinion it would have been more equitable to include some of the older small hospitals, such as this, with the large hospitals for some proportional additional grant. We trust that the pressing appeal of the Speaker will have its legitimate effect and that those who generously respond to it will do so with some effective conditions providing against the demoralising abuse of such charities. Hospitals do not need, and are not the better for, a huge and excrescent out-patient department. So fair an advocate as the Speaker will apply another test to the hospital system by which it will ultimately be judged—its indirect effect in so educating the medical profession as to make it efficient and humane. The number of persons receiving the direct charitable assistance of hospitals is very much greater than the number needing it. It says little for the hospital system of the present day if the men whom it trains cannot meet the needs of a large number of the patients now attending hospitals but having little claim on charity. We shall not be misunderstood in thus qualifying the eloquence of the Speaker and his statistics. We are the more compelled to be critical as the right honourable gentleman entirely overlooked the question of hospital abuse. We assure him of our entire concurrence in his essential purpose.

THE DANGER OF VEHICLES WITHOUT LIGHTS.

THE enormous advances which have been made of late in the methods of highway locomotion have rendered the regulations in regard to the vehicular traffic on the public roads in many districts quite obsolete. The advent of the bicycle with practically silent gear and rubber tyres soon showed that in the absence of the clatter of wheels and hoofs some other indication of approach should be enforced and a bell and lamp were properly insisted upon as necessary accessories of these vehicles. It was not long, however, before those using ordinary carriages saw the advantages of a rubber or noiseless tyre and when these advantages came to be applied the same regulation obtained. To this day, however, there is no regulation—except in a few districts—providing for the carrying of a lighted lamp on the ordinary cart, the only reason for this somewhat extraordinary exception being apparently because it is thought that the existence and position of a cart can be fairly gauged from the combined noise of the wheels of the cart and the horse's hoofs. In districts where a regulation does exist it is very seldom acted upon. As every cyclist knows it is most difficult to tell on

dark nights the exact whereabouts of a lightless vehicle and to decide whether it is approaching or receding. The risk of collision would, of course, be completely avoided if all vehicles were compelled to carry a light on the "off" side. Why cannot such a regulation be carried into effect and be universal? The danger is no imaginary one. With the greatest care a cyclist, for example, may be proceeding at night down-hill, aware that there is something ahead, but by no means sure in what direction it is going, with the result that he may suddenly find himself in contact with a powerful horse. The horse is probably startled, rears up and bolts, or kicks out and causes considerable fright if not actual injury on both sides. We know of instances of this kind where that particular offender the market-cart has been the cause of disaster. It too often happens that the carter is fast asleep. There is daily a stream of this sort of traffic to and from the vegetable markets of London within a twenty-mile radius. In consequence of carrying no lights or of a regulation to this effect not being properly enforced this is a source of constant danger to the riders of noiseless vehicles, bicycles, &c., upon the road. A regulation should be enforced and made to apply to all vehicles in every part of the country. It is quite absurd in this respect to attempt to classify vehicles using the public road; all without exception should be compelled to carry visible signals which will point the proper course to steer and thus ensure the safety of the public both on foot and on wheels.

THE PLAGUE IN INDIA AND CHINA.

WHILE the plague is declining at Bombay we regret to say that it is extending in other parts of India, as in the Nizam's dominions and at Karrachi and elsewhere; some cases have occurred also in the Punjab, at Jullundur, and what may have a more serious significance, many cases of bubonic plague have made their appearance at Calcutta. Calcutta is, we need scarcely say, a large and densely populated city and, like all large Eastern cities, not in a satisfactory sanitary condition. It is estimated that owing to the alarm occasioned by the reported appearance of plague, some 250,000 of the inhabitants have made their exodus from Calcutta. Intelligence has also been received at the Colonial Office from Hong-Kong regarding a recrudescence of the disease there. The latest telegraphic report, dated the 2nd inst., shows a slight decrease in the numbers compared with those of the previous week, but there were nevertheless 119 cases of plague with 114 deaths during the past week. Bubonic plague and small-pox have likewise been prevailing for some time among the Chinese in the colony of Macao, although not to an epidemic extent apparently. We have always and from the first regarded the occurrence of plague in India as a most serious matter, compared with which the famine and the Indian frontier war were much less important, because a plague epidemic was likely to have its recurring periods of seasonal activity and comparative dormancy and to last for a long time and because of its liability to be widely spread by the exodus of alarmed people from infected localities. It is quite probable that the infection would not gain any foothold in wholesome situations where the sanitary surroundings were good, but these conditions do not commonly obtain in the East. The disease-cause or micro-organism seems to depend greatly upon some localising influences and fostering conditions and, under such circumstances, to retain its vitality and renew its manifestations over considerable periods of time. Apart from the grave trade and commercial losses and inconveniences as well as the loss of life which the disease causes, the preventive measures which have had to be adopted have given rise to very serious discontent and opposition on the part of the native population. The authorities in India have had to grapple with a very hard and difficult problem; but they seem to be earnestly taking all reasonable precautions in dealing with it, and bad as the plague has been in India its effects and proportions have been on a very different scale in that country to those of which we have historical records elsewhere.

"THE LANCET" OF LAST WEEK.

A LARGE portion of the issue of THE LANCET of April 30th was destroyed in consequence of a fire which broke out early on Friday morning the 29th in premises adjoining those in which THE LANCET is printed, but which unfortunately was not got under until it had attacked the building where THE LANCET was undergoing the final process of being machined and bound. Work was necessarily suspended for many hours, printing- and folding-machines were flooded with water, hundreds of sheets already printed were ruined, and much delay resulted. The proprietors of THE LANCET regret the inconvenience caused to many readers by the non-receipt of their copies at the usual time and also the great trouble to which newsagents were put by making repeated applications for their supplies.

BLOOD PARASITES.

AN interesting paper by Dr. E. W. von Tunzelmann appears in the Medical Reports of the Imperial Maritime Customs for China for the half year ending Sept. 30th, 1896, which have only been recently published. He describes "a non-malarial remittant fever" which has to be discriminated from typhoid fever, with which, he believes, it has been confounded, for it appears to be a common enough disease. On examining the blood of patients suffering from the fever Dr. Tunzelmann found parasites which have hitherto escaped detection. He first observed them in a very complex case, the non-malarial remittent fever to which the fatal issue was due being mixed with a malignant form of malarial quotidian. Excellent plates accompany the article showing the various forms of the parasite. The first figure shows various stages in the development of the pigmented quotidian plasmodium of the so-called "summer-autumn" fever of the Italian observers. This form rapidly decreased in number, while at the same time infested red corpuscles became more and more abundant. The most striking of these novel appearances was that of a brilliant, double-contoured crescent, varying in size from a barely perceptible dot up to two-thirds of the size of a red corpuscle. When the focus was lowered the crescent became clearly defined, while the outline of the red corpuscle was still indistinct, as if it were external to the latter. This Dr. Tunzelmann believes to be only an optical appearance due to the high refrangibility of the parasite. The second form of organism was found on diluting a drop of fresh blood with an equal volume of normal salt solution. A couple of flagellated bodies in active movement were first seen (malarial parasites), then an object in active internal movement came into view. The greater part of it was occupied by two very clearly defined tentacle-like objects, each bent on itself, its free end swollen into a knob and attached at the other end to an ill-defined, reddish-brown body. These two were in constant motion. After two hours the field of the microscope was occupied by some twenty large objects, some of which are represented in the plates. They were in such continuous and active movement that they were difficult to sketch. These bodies are not easy to describe and vary so in appearance that without referring to the drawings no accurate idea of the parasite can be obtained. Dr. Tunzelmann proposes to call these organisms the "medusa

sanguinis hominis." He then proceeds to describe a third form of parasite which he has found associated with the medusa. These parasites are simpler in form, being usually reniform. A most notable fact about them is the enormous number which the blood may contain without producing any obvious symptoms—sometimes none at all—a point on which they differ entirely from the medusa sanguinis hominis. He has found the medusa in 4 adults and in 4 children; in every case there was pyrexia which only ceased when the medusa had completely disappeared from the blood. The other parasite he found in 21 adults and in 10 children, or, excluding those who also had the medusa, in 17 adults and 6 children. Of these, 4 adults only and 2 children had fever lasting in each case from two to four days; it was never high, 103°F. being the maximum in the adult cases, nor were the other symptoms severe. 3 of the infected adults had never had malarial fever and 4 of the children. These observations are very valuable. No doubt Dr. Tunzelmann's work will receive due attention from other workers and it promises to be of aid to treatment. Methylene blue produced better results than quinine.

THE DWELLINGS OF THE POOR.

AFTER fourteen years' work the Mansion House Council on the Dwellings of the Poor are able to take a more optimistic view of the future than hitherto. The population of the metropolis increases so rapidly that the task of attempting to guard the poor of London against disease and death in consequence of the ignorance or criminal negligence of landlords in allowing dwellings to exist in an insanitary state is a prodigious one, but the persistence and patience of the council is at last bringing its reward. The council, which works in conjunction with the London County Council and the various local authorities, has during the year 1897 made 8002 inspections, dealing with 4908 houses. Of these the council was able to get defects remedied in 2042 cases, 1335 were dismissed as trivial, &c., and 1531 were still under consideration at the close of the year. A feature of the year's work was the organisation of popular lectures on hygiene in various districts. These lectures were given merely as an experiment, but as they seem to have been successful it is probable that this new branch of work will be continued. Applied sanitary science has made and is making great progress, but until the public are taught to properly understand the meaning and benefit of hygienic laws this progress must be to a great extent retarded.

OMNIBUS CALLING-STATIONS.

THERE are certain points in the busy thoroughfares of London at which the omnibuses stop to take up or set down passengers. These were commonly situated at the intersection of two great streets. Piccadilly-circus, Ludgate-circus, and Wellington-street, where it crosses the Strand, are examples. But as the traffic increased the police found that it was expedient to prohibit the omnibuses stopping immediately at the corners, inasmuch as vehicles, including other omnibuses, frequently accumulated behind the stopping omnibus, thus blocking the traffic on the cross road, besides that going in the same direction. So that now the omnibuses are compelled to stop at a point 50 yards or so further on, and much of the previous obstruction is thus avoided. An omnibus-driver pulling up at such busy corners as we allude to would now be summoned as he is officially warned not to do so. But there are not a few people who do not know this and they wonder why an omnibus does not stop close to these points in response to their signals. Accidents sometimes arise from this misunderstanding. Persons may be constantly seen following an omnibus and attempting to enter it when it is moving under the impression that it is soon going to stop in obedience to their indications. They may manage to get in safely or they may not, or they may be left in the middle of the road in the centre of a most bewildering mass of vehicles. What we should like to suggest is that the London County Council should put up posts at the usual stopping places with an announcement intimating that the spot is an omnibus calling-station. This would save considerable annoyance, inconvenience, and exhibition of temper, not to say risks, to those persons who do not know where the omnibuses are authorised to stop.

KING'S COLLEGE HOSPITAL.

THE festival dinner of King's College Hospital was held on Tuesday last at the Whitehall Rooms, Hôtel Métropole, Lord Lister being in the chair. A large number of the supporters and friends of the hospital were present and more than a hundred letters of regret at inability to attend were received. Donations and subscriptions amounting to £3025 were announced, including one of £1000. This is the largest sum which has been collected at any festival dinner of the hospital, except on the occasion when the Prince of Wales presided.

A WEST LONDON HOSPITAL DINNER.

AT the suggestion of several past members of the visiting and resident staff of the West London Hospital it has been arranged that the past and present members of the staff, residents, post-graduates, and dressers of the West London Hospital should dine together at the Trocadero Restaurant on Tuesday, May 31st, at 7.30 P.M. The chair will be taken by Mr. Alfred Cooper, consulting surgeon to the hospital. Mr. L. A. Bidwell, 59, Wimpole-street, is acting as honorary secretary to the executive committee, and he will be glad to hear at their earliest convenience from all qualified to attend the dinner.

LEPROSY IN HAWAII.

DR. J. ASHBURTON THOMPSON, Chief Medical Officer of the Government of New South Wales, has recently published a pamphlet on the results of a critical inquiry which he made into the etiology and spread of leprosy in Hawaii. The paper appeared in an abbreviated and uncorrected form in the third volume of the Transactions of the Leprosy Conference, Berlin, 1897. After describing the geographical position, meteorology, population, and foreign relations of the group of islands Dr. Thompson considers the question of imported labour from leprosy areas, but finds little evidence in support of the theory that the disease was introduced in that way. The first reliable observations on the occurrence of leprosy in Hawaii were made between 1855 and 1863, but the rate of its diffusion is very uncertain. Dr. Thompson remarks: "All competent witnesses hold the following opinion—that there is no record or distinct tradition of the invasion of the disease. When attention was first attracted to it cases existed in every island of the group; it is not known or suggested either that any island was attacked long before the rest or that any remained free after the rest were known to suffer." It is thought at the present date by those at Honolulu who are in the best position to judge that the outbreak is now declining. The evidence that this is so is not as yet such as can be easily apprehended by the foreign visitor, and it is the case that during the last thirty years a similar opinion has been expressed from time to time only to be contradicted a little later by acknowledged facts. Great difficulties have been experienced in carrying out a policy of isolation. In 1865 the necessary land was acquired, which thenceforward became known as the Settlement, but for many years constant communication was carried on between the lepers and

their friends on the other islands. Consequently, the author says, no account of the fluctuations of this endemic can be written; all that can be furnished is a statement of the number of persons annually removed to the settlement, and this is given for the term of years from 1866 to 1895 in a table. But these numbers stand in no known relation to the total affected in the whole group and fluctuate largely, if not exclusively, in correspondence with terms of greater or less executive energy, and are hence of little scientific value. In fact, as Dr. Thompson himself observes, the value to etiology of the present case must be classed scientifically as "unobserved," as no records were kept of the original inhabitants of the islands who became lepers, but the vast majority of cases were observed in those families whose ancestors had been imported into the islands.

MEASLES AND THE PUBLIC HEALTH ACT.

AT the meeting of the Vestry of Chelsea, held on May 3rd, Dr. Louis C. Parkes, the medical officer of health, stated in his report that during the past five months an epidemic of measles had been in progress in Chelsea and other parts of London which up to date had caused some 70 deaths, in Chelsea chiefly, of infants under the age of five years. These epidemics recur with great regularity every other year. In the past major epidemics had recurred every fourth year with a minor one midway between them. The disease, though a very fatal one, is not notifiable under Section 55 of the Public Health Act, neither is it one of the "dangerous infectious diseases" under Section 58 to which the "prevention clauses" apply. Dr. Parkes thought that it would be no good notifying measles under Section 55, but he advised the vestry to concur in the action suggested by the London School Board to the County Council that the latter body should order measles to be scheduled under Section 58 so that the "prevention clauses" would apply. Thus some measures towards avoiding the spread of infection could be taken. It would also, Dr. Parkes thought, be very advisable to exclude all children under the age of five years from public elementary schools during the progress of an epidemic of measles.

THE HEATING OF RAILWAY CARRIAGES.

WE have received from a correspondent a long memorandum embodying sundry complaints in reference to the above matter, which is evidently a serious one to him. He specially objects to the system adopted on some lines of heating carriages by allowing steam to pass through iron pipes fixed under the seats of the carriages, for, according to him, they produce pathological effects of the most varied and pernicious kind. Our correspondent's zeal on this matter is, however, not according to knowledge, so we shall say no more on these points. With one complaint of his we are in accord, and that is with regard to the fusty smell produced by the slow combustion of dust and organic particles which settle on the pipes. This defect might be easily got rid of, though, by some slight alteration in the ventilating arrangements of the carriage or even by opening the window, a procedure not always fraught with such disastrous consequences as our correspondent implies is the case. He is all for a return to the old system of foot-warmers which, he says, the passenger could get if he wanted and do without if he did not. In our experience the passenger who got in a train at an intermediate station other than a place such as Swindon or Crewe could never get a foot-warmer, and the same was the case with the unhappy suburban traveller, who was frequently boxed up in a wooden case called by courtesy a carriage for some two hours while performing a journey of fourteen miles or so. So far as we know most of the steam-heated trains at present are "corridors" and there is no difficulty in opening the inner doors or the outer windows and so getting air without draughts. Another complaint our correspondent makes is that the handle which is supposed to shut off the steam will never work. This of course should be altered. The system works perfectly well on the Russian and German railways and there is no reason why it should not work equally well in this country.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE CORPORATION DUTY.

THE Customs and Inland Revenue Act of 1885 enacted that all corporate or incorporate bodies should pay a duty of 5 per cent. on the annual value of all their real or personal property unless the property was applied for the promotion of education, literature, science, or the fine arts. Relying on this last clause the Council of the Royal College of Surgeons of England have claimed complete exemption from the duty and the Commissioners of Inland Revenue allowed the claim so far as it related to the museum, but maintained the assessment on the remainder of the property of the College. Altogether they assessed the College at £3161 and required £158 1*s.* as duty. Against this assessment the College has appealed and the Court reduced the assessment by £250, the annual value of the curator's house, but declined to exempt the library from the tax because "it had not been shown that the library was applied for purposes of science." We acknowledge that there seems to be some reason for the non-exemption of those portions of the College which are used for examinations, though it may very well be maintained that they are employed "for the advancement of science," but we must confess we are much surprised at the refusal of the Court to exempt the library. It is probably one of the most valuable scientific libraries in this country and admission is more easily obtained to it than to the library of the British Museum. It can hardly be said that special privileges are granted to the Members of the College, though this seemed to be the ground on which it was held that the library was not applied for the advancement of science.

THE SUPPLY OF MILK OF PRESCRIBED COMPOSITION.

IN the artificial feeding of infants it is well known that the requirements vary with different individuals. This fact has led to the preparation of humanised milk of two different strengths, their composition differing chiefly in regard to the proportion of proteids, the other constituents being kept at about the average found in human milk. This idea has recently been extended by the Aylesbury Dairy Company, who now prepare humanised milk of a composition in accordance with that upon which the physician may see fit to decide. Thus milk may be obtained containing any prescribed percentage of fat, milk, sugar and proteids. The proteids may be either those normal to cow's milk (i.e., casein and albumen in the proportion of seven to one) or modified by a special proteolysing (not peptonising) process so as to be more digestible and to give a more finely divided curd when acted on by the milk-curdling enzyme of the stomach. The reaction to litmus paper may be either the normal amphoteric one of cow's milk or the faintly alkaline one of human milk. Another important step in advance consists in supplying separately (1) a small bottle containing cream in which the total amount of fat is ½ oz. (or any definite amount); (2) a bottle containing separated milk or proteolysed milk (as prescribed); and (3) a bottle containing a solution of milk sugar in distilled water, together with any alkali, &c., prescribed. This system obviates the changes which occur in milk in transit, especially in hot weather, and chiefly in regard to the churning and separation of the cream into butter. The quantities in (2) and (3) can

be adjusted so that on mixing the entire contents of the three bottles one pint of humanised milk will be obtained; or bottles containing 10 oz. can be supplied, so that the medical man can vary the composition by directing that the contents of (1) be mixed with measured quantities of (2) and (3). Directions as to the quantities to be mixed in order to obtain milk of definite composition are issued. Analyses are made free of cost by the company of any samples of human milk submitted by medical men, who may thus be guided as to the proper course to adopt. It must be recognised that important departures of this kind could not be undertaken without an excellent equipment at the farm and dairy. That this is so is obvious from the fact that the farms are periodically inspected by the medical officer of health for the district. The water-supplies are under similar supervision and every precaution is taken to draw milk from none but healthy cows.

A DINNER TO DR. W. S. PLAYFAIR.

WE have already announced that a complimentary dinner will be given to Dr. Playfair on his retirement (after thirty-five years' service) from hospital work by his colleagues, former residents, and friends, and that Lord Lister will take the chair on the occasion. The dinner, it is now arranged, will be held in the "Walnut" Rooms at the Grand Hotel on Saturday, June 4th, at 7.15 P.M. The following gentlemen, in addition to the staff of King's College Hospital, have expressed a wish to be present on the occasion:—Right Rev. Bishop Barry, Sir Samuel Wilks, Sir Joseph Fayrer, Sir William Broadbent, Sir William Priestley, M.P., Sir Walter Foster, M.P., Sir Dyce Duckworth, Sir Felix Semon, Dr. Farquharson, M.P., the Rev. Dr. Robertson (Principal of King's College), Professor Clifford Allbutt, Dr. Cullingworth, Dr. Buzzard, and many others. No special invitations have been issued, but any gentleman wishing to be present can obtain a dinner ticket by applying to Dr. John Phillips, 68, Brook-street, Grosvenor-square, W.

STREPTOCOCCIC PNEUMONIA.

BESIDES the pneumococcus of Fraenkel other organisms have been found in the sputum and lungs of the subjects of pneumonia; for example, Friedländer's bacillus, the influenza, the typhoid, and the diphtheria bacillus, the staphylococcus pyogenes, and the streptococcus. It has therefore been suggested that when a case of pneumonia runs an atypical course some other infection than the pneumococcus may be present. But no attempt has been made in this country to differentiate what is ordinarily called "pneumonia," which is the name of a lesion and not of a disease, into the various diseases of which it may be a manifestation. In the *Boston Medical and Surgical Journal* of April 14th, 1898, Dr. F. P. Denny calls attention to a type of pneumonia depending on streptococcus infection, described by German writers, of which he saw two cases in Vienna. The onset may be like that of ordinary pneumonia, often it is less sudden. The sputum is more purulent and is less often "rusty"; besides the streptococci pneumococci are often found. The appearance of the patient is characteristic: there are less flushing of the face and a peculiar septic look. The temperature is irregular. There is often no crisis, but the temperature comes down by lysis, often after a course of three or four weeks. The physical signs usually appear late and the upper lobes are more frequently involved than in the ordinary form. The local process has a tendency to wander. So marked is this that it has been called "erysipelas of the lungs." The most characteristic feature of all is the long duration of the physical signs. Dulness, bronchial breathing, and moist râles may often be heard six or seven weeks after the onset of the disease. There may be great prostration and it is often months before the patient has recovered from the severe sepsis. A series of 39 cases of croupous pneumonia reported by Weismayr well illustrates these points. In 34 pneumococci were found alone; in 5 there were streptococci, twice with pneumococci and three times alone. In all the pneumococcus cases with one exception resolution took place by the twelfth day, whilst in not a single streptococcus case did this occur before the nineteenth and in one not until the fortieth day. According to some writers the original infection may always be with pneumococci, but it is the streptococci which modify the disease and give the characteristic features. Pneumococci are very short-lived, whether growing in animals or on media, and if an active process goes on in the lung for more than two weeks it is fairly certain that some other organism than the pneumococcus, probably the streptococcus, is present. The diagnosis of streptococcic pneumonia must be based on the presence of the streptococcus in the sputum; typhoid fever, influenza and tuberculosis have to be excluded. The prognosis is better as regards life than in ordinary pneumonia, but, as stated, a longer course is to be expected. Treatment by anti-streptococcic serum suggests itself, but no information on this point is at present available.

A STILL UNCHECKED FRAUD.

THE prospects of a new Adulteration Bill being introduced and passed are remoter every day. We have expressed again and again the opinion that thus it would be. It was not difficult to foresee that such would be the case, there are so many interests implicated one way and another. The new Bill should, of course, embody what is perfectly fair to both the trader and the public, and he will be an astute statesman who is able to successfully establish a satisfactory balance between the two. Mr. Chaplin was asked last week in the House of Commons when he would introduce a new Adulteration Bill and the answer was, "As soon as he saw any prospect of making progress with the measure." On Tuesday last the answer was much the same and just as comfortless to a large and influential deputation representing the agricultural interests of the country. The members of this body urged upon the Government the necessity of legislative aid in order to suppress the adulteration of dairy products. They agreed with the recommendations drawn up by the Select Committee. Mr. Chaplin held out no shadow of hope; on the contrary, he admitted a divergence of opinion with the views expressed by the deputation. Meanwhile adulteration proceeds apace; the customer asks for and expects to be supplied with butter, but gets an article consisting probably of one-tenth butter and nine-tenths margarine or not unlikely ten-tenths margarine. We do not question the wholesome and nutritive value of margarine, but it is not butter. And the producers of pure butter are thus most severely and unfairly handicapped in the struggle for existence and in attempting to provide the community with a genuine article. How long is this iniquitous procedure to be tolerated?

"TRAUMATIC RUPTURE OF THE INTESTINES."

WITH reference to an annotation on this subject in our last issue we learn that there is now in St. George's Hospital, under the care of Mr. G. R. Turner, a man, fifty-eight years of age, who was operated upon for traumatic rupture of the intestine some four weeks ago, a radical cure for hernia being performed at the same time. The rupture was caused by a blow on the abdomen from a roll of sheet lead weighing 2 cwt. The ruptured bowel was not in, nor had it been in, the hernial sac. It was free in the abdominal cavity, the hernial sac being unoccupied except by a small portion of

uninjured adherent small intestine. The radical cure for the hernia promises at the time of writing to be successful; and with the exception of some bronchitis, which was present before the operation, the patient recovered without a ad symptom.

THE DANGERS OF CHEMICALS IN TRANSIT.

WE ventured to call attention in a leading article in our issue of March 23rd, 1895, to the new risks to which the public were exposed by the increasing use of chemicals in the arts and industries and by the conveyance of the same along our highways both on land and sea. Our remarks were based on what were then recent events of the following description. The explosion of coal gas under the street pavements actuated by the sparking of defective electric mains, the bursting of a steel cylinder containing compressed oxygen at a railway station, and a disaster which occurred on board a steamer through the intermingling of certain chemicals, which was brought about by the constant shipping of heavy seas shattering the vessels in which the chemicals were contained on deck. In the first instance a horse was killed, in the second a man was blown to pieces, and in the third two lives were lost in consequence of suffocating fumes finding ingress into a sleeping compartment. Another occurrence very similar to the last is reported as having recently happened to a Liverpool steamer, but in this case there was a most extraordinary collection of corrosive, explosive and inflammable substances comprising part of the deck cargo. Thus there was sulphuric acid in company with potassium chlorate and phosphorus, materials of a highly and spontaneously explosive mixture. In close proximity to these were benzine, collodion, and spirits of wine. Of six men in the stokehold and engine-room one was suffocated and the other five were burned more or less severely in reaching the deck. The vessel had to be abandoned and in the attempt to put off three men were drowned, the rest after much privation being ultimately rescued by a passing vessel. We are glad to find that a Board of Trade inquiry has been opened, and we trust that something definite will be done to prevent the indiscriminate stowing of chemicals which are most dangerous when united. For the guidance of shippers, stevedores, and others we would suggest that a list should be drawn up and printed by the Board of Trade showing those chemicals which should not be placed in close proximity to each other.

AUDITORY HALLUCINATIONS IN OTITIS MEDIA.

AFFECTIONS of the ear may produce tinnitus in its various forms, but not elaborate sounds or hallucinations; the latter are symptoms of brain disease. The explanation is simple; there is no mechanism in the ear capable of generating the highly complex sounds of language. Though absolutely correct and requiring no qualification the preceding statement does not completely state the case. If the condition of the brain be abnormal the impulses generated by disease of the ear may be a factor, and a necessary one, in producing the derangement of the auditory centre which shows itself in hallucinations. The following case, published in the *Archives Générales de Médecine*, April, 1898, by Dr. L. Coronat, is a very interesting example of this complex causation. A young man, aged twenty-one years, in good health, engaged in dissipation and did not go to bed for two nights. On the following day he travelled by train, exposing his left ear to a draught. He perceived no noises in the ear, but gradually louder and louder he heard the voice of his mother (who was dead) reproaching him with his conduct. The voice was always heard in the left ear, which he thought singular. A few days afterwards as the symptoms persisted he sought advice. The right ear was normal. The left ear showed all the signs of otitis media, the membrane was retracted, and the handle of the malleus appeared to be red. Inflation of the tympanum was practised, which gave rise to numerous râles. Under treatment gradual recovery of the ear disease took place and with it the sounds gradually disappeared. The dependence of the hallucinations on the ear disease is very evident and the requisite brain condition was produced by the strain on the nervous system of a patient who appears to have been naturally of neurotic tendencies.

THE Medical Society of London will give a Conversazione at the rooms of the society, 11, Chandos-street, Cavendish-square, on Monday, May 16th. An Oration, the subject of which will be "The Moscow Congress—a Holiday—with Comments on Suggested Topics," will be delivered by Dr. Frederick T. Roberts at 8.45 P.M. Smoking and music by the "Bijou" Orchestra will form features of the entertainment.

ON May 12th the Duke and Duchess of Marlborough will pay a visit to the Epileptic Colony at Chalfont St. Peter for the purpose of laying the foundation-stone of a new home for boys and opening "Victoria House," a new home for men. Mrs. Passmore Edwards, the wife of the donor of all these three buildings, will also open a new house for girls. The ceremony will commence at 2.45 P.M.

AT the Brompton Hospital for Consumption on Wednesday, May 11th, at 4 P.M., Dr. C. Theodore Williams will give an address on the "Open-air Treatment of Consumption as Practised in German Sanatoria." We are requested to state that all medical men will be admitted on presentation of their cards.

THE annual conversazione of the Royal Society will be held on Wednesday next, May 11th, at Burlington House.

REPORT OF THE ROYAL COMMISSION ON TUBERCULOSIS.

II.—MEAT.[1]

ALTHOUGH, as was stated in the preceding article, the Commissioners consider that there has been a tendency to exaggerate the danger from the consumption of tuberculous meat, little fault will be found on the part of the medical profession and general public with their recommendations on the subject of meat inspection. Their recommendations, indeed, have the advantage on this point even more than in the case of milk of being applicable to the whole subject of meat inspection throughout the country. They had the advantage during their continental tour of seeing in the best appointed abattoirs the routine system of meat inspection as carried out in them by veterinary surgeons, which brought into relief the chaotic (the word is used by the Commissioners) equivalent existing at home. In this country there is no uniformity of practice. A carcase with an amount of tuberculosis in it which is considered by one medical officer of health sufficient to justify seizure will by another be readily passed as fit for food. Such a state of things has naturally led to very great friction between medical officers of health and meat traders. The Commissioners have considered that this question of the extent of tuberculosis in a carcass which should warrant seizure was one of the principal points which they were called upon to decide. They therefore recommend total seizure of the carcass in cases of (*a*) miliary tuberculosis of both lungs; (*b*) tuberculous lesions on the pleura and peritoneum; (*c*) tuberculous lesions of the muscular substance or of its

[1] No. I. was published in THE LANCET of April 30th, 1898.

lymphatic glands; (*d*) tuberculous lesions in an emaciated carcass; and condemnation of the tuberculous portions only in cases of (*a*) lesions confined to the lungs and thoracic lymph glands; (*b*) lesions confined to the liver; (*c*) lesions confined to the pharyngeal lymphatic glands; and (*d*) lesions confined to any combination of the foregoing, but collectively small in extent. These rules, if acted upon, as we have no doubt they will be, would remove much of the grievance of which butchers complain. The presence of miliary tuberculosis in the lungs or muscular substance points unmistakably to the generalisation of the disease and where the carcass is emaciated, quite apart from the presence of tuberculosis, the meat cannot be nutritious. There can be no question, therefore, that carcasses thus affected should be seized. Tuberculous lesions of the pleura and peritoneum, however, are generally mere extensions of the local process from the lungs or intestines and, striking though the appearance presented by them may be, expert opinion in Germany rather tends to disregard them in judging of the fitness of a carcass for food. The recommendations are not so liberal as are those issued in Prussia and Saxony, for instance, for the guidance of meat inspectors, but as in those states arrangements are made for cooking or sterilising meat affected to a certain degree with tuberculosis it is evident that with this additional safeguard much more meat may be allowed to come upon the market than is possible where, as in this country, no such arrangement exists. The Commissioners say that they were favourably impressed with what they saw in Germany of the institution known as the Freibank, a place where, under careful supervision, the sale of this cooked or sterilised meat is carried on. It is generally thought that there would be no market for the sale of such meat in England, but the same view was held by many in Germany before the experiment was tried. Now the demand for it exceeds the supply.

Closely associated with the subject of the extent of tuberculosis in a carcass which should justify seizure is that of the qualifications of meat inspectors. The butchers, we believe, would welcome inspection of their meat provided that they had confidence in the knowledge of the inspector; but they object to be at the mercy of persons who have had no training in the diseases of animals, and that such responsible work as meat inspection should be assigned to the ordinary sanitary inspector is ridiculous. In Hackney, for instance, the report states, quoting from a Parliamentary return, the office of meat inspector is discharged by persons whose previous occupation had been as follows: two had been plumbers, one a carpenter, one a compositor, one a bricklayer, one a florist, one a builder, one a surveyor, and one a stonemason. Only in isolated instances have either butchers or veterinary surgeons been appointed, with the result that the Commissioners have had to seek exact information as to the prevalence of disease among different classes of animals from the annual reports issued from Continental abattoirs, the management of which has been placed for years with great success in the hands of members of the veterinary profession. To secure the desired end of uniformity in the practice of meat inspection the Commissioners recommend that, wherever practicable, veterinary surgeons should be employed, but whether the inspectors appointed be veterinary surgeons or not, they should all pass an examination and receive a qualifying certificate from a central authority before appointment. Recent public health legislation is tending in this direction. Local authorities have not sufficiently recognised as yet the services which a competent veterinary surgeon can render to public health. The Public Health (Scotland) Act, 1897, introduces the name of a veterinary surgeon into the sanitary service by saying that in addition to "the medical officer or sanitary inspector a veterinary surgeon" may act as a meat inspector and that "in the case of any proceeding with regard to a living animal the medical officer or sanitary inspector, unless he is himself a qualified veterinary surgeon, shall be accompanied by a veterinary surgeon."

But the Commissioners consider that a necessary preliminary to a uniform and equitable system of meat inspection is the use of public slaughter-houses in populous places to the exclusion of all private ones. Their recommendations on this point, that power should be conferred on local authorities to declare, as soon as they have erected a public slaughter-house, "that no other place shall be used for slaughtering, except that a period of three years be allowed to the owners of existing registered private slaughter-houses to apply their premises to other purposes," will be regarded by medical officers of health who have fought this point for years as eminently satisfactory. Cases are cited in the report where the public slaughter-house, admirably equipped though it be, has proved itself a white elephant from the unreasonable prejudice on the part of butchers in favour of private over public slaughter-houses. They also recommend that all meat slaughtered elsewhere than in a public slaughter-house and brought into the district for sale should be taken to some place for inspection. It is to be hoped that these recommendations will before long lead to legislation so that no further obstacle will be placed in the way of the erection of public slaughter-houses in all large towns. The Commissioners are of opinion from the inspection which they made of the public slaughter-houses in Edinburgh, Glasgow, Belfast, and elsewhere in the United Kingdom that the separate chamber system on which they are constructed offers an obstacle to efficient inspection which is absent from the hall system now adopted in Germany.

In comparing the systems of meat inspection in this country with that on the continent it must not be forgotten that the conditions affecting them are very different. In addition to the fact that abattoirs are the rule in large towns abroad, home-fed cattle suffice for the meat-supply in Germany, whereas in this country we are dependent very largely on cattle imported from America to be slaughtered at the port of entry and on chilled or frozen imported dead meat, and butchers complain that this meat is not subjected to the same stringent inspection as is the case with that of home-grown cattle. The Commissioners agree that this is the case and suggest certain remedies, but the butchers overlook the fact that there is a general consensus of opinion among medical officers of health who are brought most into relation with these foreign supplies that from the open-air life the animals have lived and the fact that they are selected animals there is little tuberculosis among them. And it must not be forgotten that the animals imported from the United States and the dead meat from Australia and New Zealand have been inspected prior to shipment.

The Commissioners have been unable to agree on the subject of compensation demanded by the butchers for the seizure of the carcasses of animals which have been bought in open market for a fair price apparently quite healthy. The claim of the butchers is based on the fact that the seizure is made in the interests of the public health and they think the public therefore should pay for it; and, further, that an animal may have no sign of tuberculosis recognisable during life, but may nevertheless, after slaughter, be found badly affected with the disease. Many medical officers of health, it is well known, sympathise with the butchers in the loss which they thus at times sustain and have supported their claim for compensation. Four of the Commissioners, however—a majority of one—regard the risk of purchasing a tuberculous animal as well recognised in the trade and one that is taken account of in the purchase price. They think, moreover, that, like other trade risks, it might be easily met by some form of insurance such as has been adopted in a few towns in Great Britain and very widely in connexion either with abattoirs or butchers' societies in Germany. The memorandum signed by three of the Commissioners advocates compensation up to the full value of the animal provided that the magistrate ordering confiscation satisfies himself that the animal had a good appearance before slaughter and exhibited no visible signs of tuberculosis. The compensation is to be charged against, and paid by, the county council which shall be entitled to repayment of one-half the amount from Imperial funds. Such an arrangement would no doubt satisfy the butchers entirely, but there is a considerable danger that it would remove any incentive on his part to be careful in the purchase of his beasts, and it would be an easy means of relieving the farmer from the responsibility of taking all the measures in his power for eliminating the disease from his herd. The possibility of fraud on the part of low-class farmers and slink butchers must not be lost sight of and there can be no doubt that its prevention would be most easily effected by a mutual insurance scheme among farmers and butchers. As has been said, the hardship from losses by reason of tuberculosis has been met in Germany by insurance societies, the premiums charged being arranged so as to cover the losses. But we believe that the cattle dealer in Germany is the person who insures as he suffers the loss, payment not taking place by the butcher to him until the animal has been passed by the inspector. If

in this country the butcher were to demand a warranty from the farmer that his animals should pass the inspector the whole loss would be transferred to the farmer. Failing compensation, insurance either among the butchers or farmers alone, or both jointly, is the only alternative. Seeing that the interests of both farmers and butchers in the matter are very closely connected and that the success of an insurance scheme largely depends on securing the coöperation of all parties concerned a joint insurance fund offers the best means of meeting the difficulty. The loss from seizures of tuberculous carcasses has not been great, but being generally unexpected it has led meat traders, we think, to exaggerate the importance of the grievance.

THE BRITISH PHARMACOPŒIA.

III.[1]

OF the omissions in the new British Pharmacopœia the practitioner has little to complain. On analysing the formidable list of 188 it will be found to contain substances or preparations of practically no value or interest in daily medical work with a few notable exceptions. Everyone rejoices at the exclusion of the cataplasmata and the vapores, the enemata, and most of the decocta. Substances such as flour, breadcrumb, eggs, milk, lettuce, vinegar, cucumber, &c., which have long remained "superfluous on the stage" and which were intimately associated in the professional mind with the constituents of a salad or with the index to Mrs. Beeton's domestic pharmacopœia are now no longer stamped with the official brand.

The only regret which can be entertained concerning this part of the work is that the list is not at least twice as long and then all traces of senility would have been removed from our national Pharmacopœia.

All the infusions should have been omitted save digitalis and a single paragraph inserted in their stead directing in general terms that a fresh infusion of any vegetable drug could be prepared by infusing a given amount—say 1 oz.—of the comminuted substance for fifteen minutes in a pint of boiling water and straining, exceptions being made in a few cases—e.g., quassia and calumba.

We would also venture to suggest that the confectionery department might well have been entirely omitted or else seriously curtailed. The lozenge is a rather mediæval form and we find no less than 17 of them. However, we must be thankful that the lozenge of opium is omitted and that 4 of the old confections have disappeared—i.e., opium, hips, scammony, and turpentine. There is one omission which the practitioner will seriously regret and this is the liquor ferri dialysatus. Doubtless there is great difficulty presented to any revising committee which honestly attempts to cut out effete and worthless preparations. We believe that hardly a single preparation could be condemned without some champion entering the lists in its defence. This was well illustrated in a former revision when sumbul was suggested for the omission column. It was at once stated that the drug was much prized and sold in the West-end pharmacies and it still remains official. The case of the dialysed solution of iron is, however, very different; its place cannot be taken by any other preparation. It was non-astringent and did not blacken the teeth and could be swallowed by those who could not manage to take the reduced iron in pill form. There were doubtless reasons which influenced the revisers when they came to the decision that it should be omitted and these probably were points in connexion with its tests and strength. The drug will continue to be prescribed till a better liquid non-astringent preparation can be found and the practitioner must remember that when he now orders it he must be careful of the patient's interests by directing him to get his prescription made up at a chemist's of known repute as the old official safeguards, such as they were, are now removed. The unstable mess known as mistura ferri aromat. or Heberden's ink is wisely omitted, but the venerable mistura ferri co. with all its proneness to decomposition and unsightliness is still honoured.

But whilst deploring the omission of the dialysed liquor we must direct attention to the absurdity of retaining the vinum ferri still prepared by partially immersing 1 ounce of iron wire for thirty days in 1 pint of sherry. It is a most variable preparation, the amount of iron (which is always fractional) depending entirely upon the amount of acid present in the sherry and in the new British Pharmacopœia there is no test or standard for this acidity, hence no two samples of the wine will agree in strength. The preparation should have been omitted and the name transferred to the vinum ferri citratis. It is a strange fact that this representative of the middle ages should have appeared in Martindale's list of the analysis of 12,000 prescriptions as having been prescribed fifteen times whilst vinum quininæ was not once ordered. In the same number of prescriptions the vinum ferri citratis was prescribed also just fifteen times, but it is possible that when vinum ferri was ordered sometimes the prescriber meant or intended that the citrate should have been dispensed; at any rate it is clear that this is no justification for its retention when we have another wine of iron of definite strength and recognised elegance.

The two essences—anise and peppermint—will be missed. The former especially was much employed in the colic of infancy, though it was seldom prescribed formally by the physician. The dose of the new spiritus which now takes its place is given as from 5 to 20 mins.—i.e., from ½ to 2 mins. of the oleum—a dose which is obviously useless in the majority of cases except when the patient is an infant, and then the amount of strong alcohol present in the maximum dose would represent more than a proper dose of ordinary whisky which is now always sold of the strength 20 under proof. We would therefore recommend the prescriber in such cases to order the anise oil to be given upon moist sugar in a teaspoon.

Of the Extracts the omissions are 17. In the case of 15 of these the physician will have little cause for regret, but the alcoholic extract of gelsemium will be missed, especially as there is now nothing to take its place when he wishes to treat a case of neuralgia of the fifth nerve by a recipe in the pilular form. Many will also regret the exclusion of the extract of logwood. It gave results in the diarrhœa of tuberculous peritonitis—in the pilular or cachet form especially—which justified its retention in preference to the decoction. A dose of 2 fluid ounces of a dye-stuff is not to be regarded as an advance in elegant pharmacy. We would suggest that always the dry extract of rhatany which "is still with us" should be preferred. We could have better spared the wholly inert extract of dandelion, the extracts of gentian, rhubarb, and liquorice, especially the first and the last of these, since they have also each a liquid extract. The attention of the prescriber must be called to the case of belladonna; this drug has now three extracts and the revisers have shown wisdom in arranging that the doses of the two semi-solid ones should be identical—i.e., ¼ to 1 gr. The verdict would probably have been unanimous had they seen their way to reject the old green one, especially as it now is the only preparation of belladonna which is not standardised or made to contain a definite percentage of alkaloids except in the case of the natural succus from the leaves and fresh young branches. All the other preparations of belladonna, numbering no fewer than seven, are standardised.

The omissions in the Infusions number 7; 2 of these were household remedies — viz., anthemidis and lini, but though in constant or daily use they were seldom prescribed in a recipe and the authorities are justified in their rejection, still we part with old friends with some reluctance. Our regret is, however, greater that several others were not sent to keep them company, notably serpentary, which also now has a concentrated infusion or liquor. For the same reason that linseed and chamomile were rejected ergot should disappear; it is seldom if ever ordered in a recipe, though often administered fresh, thus in Martindale's 12,000 prescriptions it was only prescribed once. We shall refer to the substitutes for infusions when treating of the new introductions to the British Pharmacopœia in a later article.

Of the 15 omissions in the Liquors the revisers have shown their judgment to be correct, in our opinion, in the great majority of cases—indeed, we may say in all except the iron preparation previously referred to which, owing to its importance, we mentioned at the beginning of this article. The practitioner must notice that since the effervescing liquors of potash, soda, and lithia are now no longer official it will be necessary when ordering them to see that the manufacturer supplies them of a definite strength.

[1] Articles I. and II. were published in THE LANCET of April 16th and 23rd respectively.

The omissions in the Pills are removals of decided blots. Hemlock was inert and the carbonate of iron and the iodide were unstable and variable in composition.

The omission of the Suppositories containing soap removes another blot and, indeed, the Pharmacopœia does not now contain one of these unnecessary preparations. It is to be noted that suppository of mercury is also omitted. When required, which is seldom, the surgeon can easily prescribe the exact amount of the ointment or mercurial which the particular case requires.

No one will lament the omission of the syrups of mulberries, poppies, and subchloride of iron, the last being one of the most recent additions to the British Pharmacopœia.

Of the 11 Tinctures excluded all were of little value but the physician will often feel at a loss for a liquid preparation of valerian in combinations containing acid ingredients, since the only one now is the ammoniated tincture. Since the strong tincture of ginger is now omitted it would have been well had the Committee increased the strength of the ordinary tincture, which is now weaker than formerly, being only 2 oz. to the pint. A tincture of double this strength would have been an important improvement. The physician will note that tincture of veratrum viride is also omitted and this is an improvement; it had no action which aconite tincture does not possess. The tinctures in the old British Pharmacopœia numbered 75, they are now 67. It will thus be seen that they are by far the most important group in the volume, and nowhere is the good work done by the Committee more apparent. They found this group, which occupies a considerable proportion of the Pharmacopœia, consisting of a list of liquids of all strengths and doses without uniformity and containing in their processes errors and directions which were not creditable to British pharmacy; they have reduced them to comparative uniformity—brought order out of chaos. As mentioned in our second article the doses are now made either to be of from 5 to 15 mins. or of from ½ to 1 dr. with the one exception of iodine.

The physician should note the change in the tincture of aconite. It was formerly made with 2½ oz. of the root to the pint; it is now made with only 1 oz. and, strange to say, the dose remains exactly the same. This is quite right—the old British Pharmacopœia dose was dangerously high; indeed, the present dose of from 5 to 15 mins. is quite high enough, but it is qualified by the important statement: "If frequently repeated 2 to 5 mins." Many physicians will prefer to give only one quarter of this amount every fifteen minutes till an impression be made upon the skin, pulse, and temperature. The next change of vital importance appears in the tinctura chloroformi et morphinæ co. This preparation now contains *more than four times the amount of morphine* present in the corresponding old tincture and very remarkable is the fact that its dose is given as larger. The old preparation had a dose of from 5 to 10 mins., the dose of the new is given as from 5 to 15 mins. The tincture of colchicum seeds is now made with 4 oz. instead of with 2½ oz. to the pint and the dose of from 10 to 30 mins. is reduced to from 5 to 15 mins. We are glad to see the tincture of digitalis unchanged, though it is the only tincture in the Pharmacopœia now of the strength of 1 in 8, but it must be noted that its dose is reduced by one half—i.e. from 5 to 15 mins. Tincture of nux vomica now contains twice the amount of strychnine contained in the old tincture, but the dose is only slightly altered, its maximum being now 15 mins. as against 20 mins. Laudanum is practically unaltered except in the process of preparation. Squill, senega, senna, stramonium, valerian, rhatany, and several others have their strengths now made 1 in 5 instead of 1 in 8 and the dose is proportionally reduced.

A noteworthy change is made in strophanthus tincture. It now contains only ½ oz of the seeds to 1 pint; this is half the strength of the old tincture and the dose is exactly the same as that of tincture of digitalis which is five times its strength. Lobelia is now 1 in 5 and is a very active preparation with the maximum dose of 15 mins. The change in the Ointments is for the better in every case. Tartar emetic, calamina, elemi, potassa sulphurata, and savin, simple ointment and turpentine are excluded. There are none of these which will arouse any feelings of regret at their omission. Most of them are only known to the bulk of the profession as items which had to be remembered at the examiner's table. The older members will perhaps be sorry to part with the ancient Turner's cerate but they may console themselves with the reflection that there are now numerous others much more suitable and reliable for the same purpose. The exclusion of the wines of aloes, opium, and rhubarb is also an advance.

In dealing with the omissions we have hitherto dealt mainly with Galenical preparations, because it has been chiefly with these that the revisers have been busy. It is a most gratifying reflection that there is not a single omission of any drug or remedial agent of even third-rate importance. Yeast, canella, animal charcoal, cetraria, nitrate of copper, elemi, guttapercha, barley, manna, kamala, mastich, matico, savin, sabadilla, treacle, raisins, marble, as well as about a dozen of crude drugs the purified representatives of which still remain, give a good general idea of the nature of the revision in this direction. The only active drug of any pretence to importance which has been omitted is green hellebore and its tincture, but veratrine obtained from cevadilla is still official and it is practically identical with the active principle of green hellebore.

Chemicals such as nitrate of lead, sulphate of mercury, cyanide and ferro-cyanide of potassium, valerianate of soda and nitrate of soda, which were only official because they were used in the preparation of other drugs, are now wisely omitted. The cinchonine and cinchonidine salts were of great importance as substitutes for quinine when this drug was from 15 to 20 times its present market value. Like many of the veterans already mentioned they have fallen honourably and must make way for valuable substances like the soluble acid quinine hydrochloride.

Tobacco is omitted, notwithstanding all that has quite recently in high quarters been done in its favour, but it was certainly an anachronism and its retention was a mistake by the 1885 revisers after its Galenical preparation had then been omitted.

By this brief summary of the omissions made in the 1898 British Pharmacopœia the practitioner will see that he has little to alter in his daily practice, and we can safely say that what little change the new volume will necessitate in his prescribing will be an advantage both to himself and to his patients.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE twentieth sitting of the Royal Commissioners was held in the Council Chamber of the Westminster Town Hall on Monday last, May 2nd. All the Commissioners were present. Sir Arthur Arnold completed his evidence and Mr. Shirley Murphy, medical officer of health for the Administrative County of London, was then examined. Towards the end of the sitting Mr. G. F. Deacon gave evidence on behalf of the London County Council with regard to the scheme for bringing water from Wales and with regard to the cost of carrying out the Staines reservoir scheme. The witness exhibited large tables showing the daily flow of water down the Thames for a series of years and contended that the storage capacity of the Staines reservoirs would have to be very great in order to ensure a sufficient amount of reserve water during periods of drought.

Sir ARTHUR ARNOLD gave evidence with regard to the payments made to the labourers employed by the Parks Committee of the London County Council. In the year 1891 the wages of the gardeners, constables, and labourers were 24*s.* a week during the winter months and 25*s.* a week during the summer months. At the present time the wages were 27*s.* a week for a week of 54 hours, that is at the rate of 6*d.* an hour. Lately the Parks Committee had decided that their employés should be paid at the same rate during the winter months although the hours of labour were 48 instead of 54 as in summer. Sir Arthur Arnold thought that the raising of the wages was a proper and reasonable course.

In answer to Sir GEORGE BARCLAY BRUCE the witness said that he did not know how the rate of wages compared with that paid by other employers of labour and remarked that the "heaviest domestic expenses" occurred to the workmen during the winter months, which was a reason for giving them the recent rise in their wages. The witness thought that the London County Council were not overworked. They had at present no arrears; there was no "obstruction." He did not consider the Council were a political and partisan body and he thought that they should be allowed

to control the water-supplies. With regard to purchase he repeated that the undertakings should be bought by arbitration, which should be "full, free, and open." He objected to purchase under the Land Clauses Act because of "technical rules" which, he said, he understood were in force when the clauses of the Act came into operation.

Mr. CRIPPS, Q.C., asked the witness to refer the Commissioners to any clause in the Act which had the significance which the witness suggested.

In answer to Mr. MELLOR he said that he understood that practices had grown up during the time in which the Act had been in force.

In answer to the CHAIRMAN he said that in the arbitration for purchase it would be quite right to consider whether any allowance should be made for compulsory purchase and that no material contention should be excluded on either side.

In answer to Mr. CRIPPS the witness said that he did not agree with Sir John Lubbock that it would be of advantage to add to the boards of directors of the water companies representatives elected by the water consumers.

In answer to Mr. MELLOR the witness said that he did not think it would be possible to compel the companies to amalgamate.

In answer to Mr. CRIPPS the witness said that he considered that the bargains made by the New River Company with their City customers were not fair. It was very unfair to have a bargain. The witness did not explain to whom the bargain was unfair—whether the New River Company were acting unfairly to themselves in not charging their full statutory prices, or whether, on the other hand, the citizens were acting unfairly in not paying to the company a larger sum than the company was satisfied to receive.

In answer to Mr. BAGGALLAY the witness said that he was not aware that the London County Council had opposed "tooth and nail" the proposition that the mains of the East London Waterworks Company and the New River Company should communicate. With regard to the interview which the witness had with the chairmen of the water companies Mr. Baggallay said he could not accept the interpretation which the witness put on the interviews which he had had with them. The chairmen had, the witness said, received him with courtesy and he had afterwards made public the opinion which he had formed, but he would not give any account of the interviews from which he had formed the opinion.

Mr. BAGGALLAY therefore asked the Chairman of the Commission what should be done to clear the matter up. The Chairman suggested that a notice should be given to Sir Arthur Arnold and that afterwards Mr. Baggallay should call as witnesses the chairmen of the water companies.

Mr. MELLOR thought that the interviews were confidential and that it would be better not to call evidence on the matter. What value, he asked, could the Commission attach to Sir Arthur Arnold's expression of opinion? and did the learned counsel suppose that such evidence would have any effect whatever on the Commissioners?

Mr. BAGGALLAY was satisfied with this expression of opinion and asked the witness no more questions.

Mr. SHIRLEY MURPHY said he thought the present system of examining the water-supply was inadequate. In his opinion the same authority ought to be the water-owning authority and the disease-preventing authority. He would have no hesitation in allowing the London County Council to have the management of the water-supply and to be free from external control in respect to its management. He did not think that those who drank water from the Thames were less healthy than those who drank water from the chalk. The death-rate from typhoid fever in London was low. At the present time there was a "feeble virus" of typhoid fever. It might be more difficult to deal with when the virus was of greater intensity.

In answer to Mr. BAGGALLAY the witness said that he believed there was an increase of typhoid fever in 1894 as a result of the quality of the water supplied from the river Lee when it was in flood, but he said it was impossible to trace typhoid fever to the water supplied either from the Thames or from the Lee. The death-rate from typhoid fever in London was less than that in any of the other large towns in England with the exception of Brighton, Bristol, Huddersfield, and Bradford. At the time of the late outbreak of typhoid fever at Maidstone the London County Council asked the London water companies to allow their medical officer and their chief engineer to inspect the companies' works. The London water companies would not allow the visits to be made.

Mr. G. F. DRACON, in answer to the CHAIRMAN, said that he was a civil engineer, that he formerly had charge of the Liverpool Waterworks, and that he had been employed by the London County Council to report on the scheme for supplying London with water from Wales. He put in a "private and confidential" report on which it was suggested that the Commissioners should examine him. His evidence dealt with the cost of the Welsh scheme and with the outlay which would be necessary to make at Staines reservoirs of sufficient capacity to last over periods of drought on the conditions suggested by the Balfour report that water should not be taken from the reservoirs during and immediately after flood or during periods of drought. The witness referred to some diagrams which he had prepared, but it appeared that these were made on the supposition that the London water companies would not draw the amount of water they do at present at the various inlets now in use.

In answer to Major-General SCOTT the witness said that if a system of control were adopted it would be necessary that storage capacity should be increased coincidently with the increase of population, that works should be added as occasion required, that the storage capacity could not be considered satisfactory if there were no reserve, and that for efficient control it was necessary that the controlling authority should have power to compel a company to have a sufficient amount of storage capacity.

In answer to further questions the witness said that there was undoubtedly a tendency to economy in the case of companies which were not rich, and that it was reasonable that the storage capacity should be sufficient to ensure a supply during periods of drought. It was desirable that the controlling authority should have a power of inquisition and a power of entry to see whether there was any falling off in the storage capacity having reference to the increase of population and the authority should have statutory power to get the necessary information; the inspectors of the authority should not be in the pay of the companies. The regulations affecting filter beds required especial care, and actual inspection was absolutely necessary to ensure efficient control.

In answer to Mr. PEMBER the witness said that the nature of the soil on which it was proposed to make the reservoirs in Wales had not been specially examined.

The next sitting of the Commissioners will take place on Monday, May 9th, at the Council Chamber of the Westminster Town Hall.

THE VACCINATION BILL AND THE MEDICAL GUILD.

WE have been asked to publish the following reasons which have been urged by a committee of the Medical Guild against certain provisions in the Vaccination Bill together with a protest concerning certain omissions:—

I.—*Against the extension of the age period.* (Section 1—(1) of the Bill).

(1) The longer period (nine months) during which the child would be unprotected.

(2) Vaccination should be well over before the commencement of teething. If it be delayed until the time of teething or of weaning the troubles incidental to those periods would by many parents be regarded as the direct effects of vaccination and would naturally develop in their minds a prejudice against the operation, which would make vaccination more unpopular than it now is.

(3) As children grow older they become more vigorous and active; consequently the movements of the vaccinated arm would be more energetic and the risk of injury and of erysipelas and blood-poisoning would be correspondingly increased.

(4) In manufacturing towns the extension of the time limit would to a great extent render the Act inoperative on account of the frequent changes of residence which occur among the working classes; many children would be lost sight of by the vaccination officers and would thus remain unvaccinated, partly owing to the difficulty and cost of tracing them and partly to the indifference of the parents.

(5) The extension of the age period is unnecessary because the existing law empowers any medical practitioner to postpone vaccination when the operation is undesirable on account of the state of the child's health.

II.—*Against the abolition of public vaccination stations.*—The retention of public vaccination stations would conduce to the greater safety and efficiency of the operation and avoid needless expense to the ratepayers.

III.—*The provision against repeated penalties* would, it is believed, render compulsory vaccination null and void and would seriously endanger the public health.

IV.—*Two omissions from the bill* are noteworthy and call for protest—

viz., (1) the absence of provision for efficient revaccination, and (2) the absence of a definition of "successful vaccination."

In order to make vaccination by both public and private practitioners more efficient and uniform than it is at the present time the form of certificate for successful vaccination should specify that not less than three vesicles have resulted from the operation.

JOHN DIXON MANN, M.D. St. And., F.R.C.P. Lond., Chairman of the Medical Guild.
R. H. WOLSTENHOLME, M.R.C.S. Eng., Vice-Chairman.
CHARLES G. L. SKINNER, M.D. Aberd., Treasurer.
ALEXANDER STEWART, M.D. Glasg., Hon. Secretary.
Manchester, April 29th, 1898.

THE SPANISH-AMERICAN WAR.

THERE can be no longer any doubt about the extent of the disaster which has befallen Spain. At the battle of Manila the ships of the Spanish Pacific Squadron have either been destroyed by the American fleet or they have been sunk to avoid being captured. The admiral commanding the United States squadron has so irretrievably defeated the naval forces in the Philippines as to have destroyed any hope of success that might have existed on the part of the Spanish Government in this direction. The work of destruction, too, has rarely been accomplished with greater thoroughness and rapidity—a rapidity which in its dramatic effect resembles the transformation scene of a spectacular play. It furnishes the strongest testimony to the dash, courage, and naval skill displayed by Admiral Dewey and his seamen that he was enabled to carry out his brilliant piece of work with such disastrous results to his enemy and with seemingly such very little injury to himself and the fleet under his command. The news of the collapse of the Spanish defence came, too, with something like dramatic surprise, for although it was well known that the preponderance of strength—in size, armament and construction—was greatly in favour of the American ships, it was thought that, what with mines and torpedoes and the guns of the Cavite forts as supplementary aids to their ships, the Spanish authorities might, at any rate, have made the task a far more dangerous and difficult one than it has proved.

The main interest of the war has now been suddenly transferred from the Pacific to the Atlantic Ocean, for the next great naval engagement—if it takes place—between the American and Spanish fleets will, if the result be adverse to Spain, be decisive. That section of the Spanish navy which has not yet been engaged is altogether the stronger portion as it comprises ships of the best construction, armament, and power in the Spanish fleet, and the United States will, if victorious, have undisputed command of the sea and the war will be virtually over. America can then afford to wait and to select the best and most healthy season for her land operations in Cuba and elsewhere.

Putting aside for the moment the effect which the attack on Manila may, indeed must, have on the course of the war, we may ask, Will the United States invade Cuba and strive to drive the Spaniards out? The embarkation and disembarkation of a large military force, such as has been contemplated by the United States, is a difficult and even formidable undertaking for an unprepared country however powerful, especially where the force has to be suddenly thrown on the lowlands of an unhealthy coast at the commencement of the worst season, to say nothing of the fact that the volunteer soldiers are undrilled and unprepared for war and that the naval victory gained by the United States at Manila does not give them command of the sea. No one who realises the nature of the task which the American Government has undertaken can disguise its difficulties; and we may be quite sure that, however much the Jingo element and the impulsive uncalculating section which exists in every population may shut their eyes to these, the President of the United States and his responsible naval, military, and medical authorities do not. Years ago this country, for pressing political reasons, equipped and disembarked a small force for the occupation of Cyprus, which is now one of the most healthy of our foreign stations. What with an exceptionally unhealthy season and the temporary want of adequate preparations a large amount of sickness from climatic fever followed for a time in the regiments encamped there; and it is only to be expected that a force landed in Cuba will undergo a similar but far worse experience. Cuba has an area of some 43,000 square miles. Its length is about 800 miles and its greatest breadth is 125 miles, but in places it does not exceed 25 miles. It consists of a low-lying country and of a rugged mountainous region, with ravines and valleys, some of the mountains having considerable altitude. Havana is about 100 miles distant from Key West and the Bay of Florida. From all we know of the island it has a very unhealthy climate during the hot and wet season, from May to October; its marsh lands are fed by underground streams. The longest river of the island, the Cauto, is only navigable for a short course. The low-lying districts are very malarious and, as we have previously said, in addition to climatic and malarious fevers yellow fever may be said to be endemic there. The country is also, in a military sense, a difficult one for campaigning, the uplands and mountainous regions offering facilities for guerilla warfare. It is obvious that a blockade, if it can only be effectively maintained, offers many strategical advantages, but its effect on the already starving insurgents, for whose sakes the United States are fighting, is likely to be disastrous. Supposing the United States to succeed in landing a force and establishing a base of operations somewhere on the seaboard of Cuba, it will, of course, have to be furnished with commissariat and warlike stores and supplies of all kinds and for this purpose, whether the force be large, or small at the first and gradually augmented, America must have and retain command of the sea. Little or nothing is really known as yet of the proposed designs and course of action of the two belligerent Powers; but, as our experience has already shown, there will, in the meantime, be no end of war rumours in order to supply pabulum for the keen appetite which exists for news. The number of medical officers and nurses will have to be large on both the Spanish and American sides, and volunteers for hospital service will, no doubt, be forthcoming now that the war has begun in real earnest. The difficulty is to obtain them of the right stamp in sufficient numbers and to select men with the requisite organising power and experience of medical administration in the field for filling responsible posts.

That the United States are fully alive to the necessity of having an efficient medical service is proved by the fact that quite recently a Bill was introduced into the House of Representatives which provided for the appointment of additional surgeons for the army and authorised the Surgeon-General to appoint as many assistants as he should deem necessary in case of war with Spain. Hitherto the age limit for entrance has been between the ages of twenty-four and twenty-eight years, but the necessity of getting competent medical men to fill naval posts at any cost has been fully recognised, and men up to the age of forty who are willing to attend to the wounded in the Spanish-American War will be received as assistant surgeons. In passing it may be noticed that the preference shown for the army over the navy has nothing to do with the rate of pay, because the naval surgeon gets a far larger salary than his army *confrère*.

On each of the American warships there is a small hospital, and the sick beds are placed between decks. Usually a man is attended to on the spot and then hoisted up or lowered down to the hospital according to where the accident takes place. After an engagement the men whose wounds require long treatment will be transferred to a hospital ambulance ship which is now being rapidly completed. Provision for 150 patients or more is to be made and there will be four surgeons, four apothecaries, and eight trained nurses (men).

At Key West a convent and some school buildings have been offered to the United States Government to be used as a hospital. The sisters of the convent have offered their services as nurses.

It may be mentioned that during the succeeding months the climate of Manila is hot and humid and relatively unhealthy, and much sickness may probably be expected to occur in any army of occupation.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6462 births and 3965 deaths were registered during the week ending April 30th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 21·5 to 18·1 per 1000, rose again last week to 18·4. In London

the rate was 17·2 per 1000, while it averaged 19·3 in the thirty-two provincial towns. The lowest rates in these towns were 10·3 in Cardiff, 13·0 in Wolverhampton, 13·9 in Nottingham, and 14·7 in Croydon; the highest rates were 22·4 in Newcastle-upon-Tyne, 26 6 in Gateshead, 26·8 in Sunderland, and 30 0 in Liverpool. The 3965 deaths included 467 which were referred to the principal zymotic diseases, against 488 and 472 in the two preceding weeks; of these, 177 resulted from measles, 140 from whooping-cough, 66 from diphtheria, 29 from "fever" (principally enteric), 28 from scarlet fever, and 27 from diarrhœa. No death from any of these diseases was recorded last week in Brighton or in Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Plymouth, and Swansea; and the highest rates in Derby, Halifax, Leicester, and Sunderland. The greatest mortality from measles occurred in Sunderland, London, Oldham, Bristol, Halifax, and Leicester; from whooping-cough in Liverpool, Newcastle-upon-Tyne, Gateshead, and Bolton; and from "fever" in Sunderland and Wolverhampton. The mortality from scarlet fever showed no marked excess in any of the large towns. No death from small-pox was registered in any of the thirty-three large towns; and no small-pox patients were under treatment last week in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in those hospitals and in the London Fever Hospital on Saturday last, was 2302, against 2421, 2384, and 2334 at the end of the three preceding weeks; 205 new cases were admitted during the week, against 234, 217, and 241 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 305 and 283 in the two preceding weeks, further declined to 274 last week and were 83 below the corrected average. The causes of 54, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Manchester, Newcastle-upon-Tyne, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Blackburn, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·5 and 22·0 per 1000 in the two preceding weeks, further declined to 21·8 during the week ending April 30th, but exceeded by 3·4 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·2 in Edinburgh and 21·1 in Leith to 26·4 in Greenock and 27·2 in Perth. The 657 deaths in these towns included 35 which were referred to measles, 34 to whooping-cough, 17 to diarrhœa, 6 to scarlet fever, 2 to "fever," 1 to diphtheria, and 1 to small-pox. In all, 96 deaths resulted from these principal zymotic diseases, against 79 and 88 in the two preceding weeks. These 96 deaths were equal to an annual rate of 3·2 per 1000, which was 1·0 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 14 and 26 in the two preceding weeks, further rose to 35 last week, of which 30 occurred in Glasgow. The deaths referred to whooping-cough, which had declined from 44 to 25 in the three preceding weeks, rose again to 34 last week, of which 16 were registered in Glasgow, 5 in Dundee, 4 in Edinburgh, and 4 in Aberdeen. The 6 fatal cases of scarlet fever corresponded with the number in the preceding week, and included 4 in Glasgow. The two deaths from "fever" occurred in Edinburgh, and the fatal case of small-pox was recorded in Leith. The deaths referred to diseases of the respiratory organs in these towns, which had been 164 and 151 in the two preceding weeks, further declined to 137 last week, but slightly exceeded the number in the corresponding period of last year. The causes of 33, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·1 and 23·3 per 1000 in the two preceding weeks, rose again to 25·4 during the week ending April 30th. During the past four weeks the death-rate in the city has averaged 25·0 per 1000, the rate during the same period being 18·5 in London and 19·4 in Edinburgh. The 170 deaths registered in Dublin during the week under notice showed an increase of 14 upon the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 10 and 13 in the two preceding weeks; of these, 3 resulted from whooping-cough, 2 from diphtheria, 2 from "fever," 1 from scarlet fever, and 1 from diarrhœa. These 9 deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 2·8 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had been 3 and 2 in the two preceding weeks, rose again to 3 last week. The 2 deaths referred to "fever," corresponded with the number registered in the preceding week, while the mortality from scarlet fever and from diarrhœa showed a decline. The 170 deaths in Dublin last week included 29 of infants under one year of age, and 53 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded the numbers recorded in the preceding week. Five inquest cases and 3 deaths from violence were registered; and 65, or more than a third of the deaths occurred in public institutions. The causes of 15, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

NAVAL MEDICAL SERVICE.

DEPUTY-INSPECTOR OF HOSPITALS R. GRANT, M.B., to Chatham Hospital. Fleet-Surgeon W. R. White, C.B., to the *Hannibal*. Staff-Surgeons: J. B. B. Triggs to the *Alexandra* and J. L. Aherne to the *Caledonia*. Surgeons: P. K. Nix to the *Hannibal*; W. Jackson to the *Rodney*; A. H. Jeremy to the *Australia*; A. Gaskell to the *Victory*; J. D. Hughes to the *Tartar*; G. Ley to the *St. Vincent*; J. K. Robinson to Bermuda Hospital; and T. E. Honey to the *Defiance*.

ARMY MEDICAL STAFF.

Surgeon-Captain Davoren is under orders for embarkation for India. Surgeon-Lieutenant E. Brodribb proceeds to Worthing for medical charge of troops stationed at Cissbury Camp.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Colonel Hunt, Madras, retires from the service, as does also Surgeon-Captain Hall, temporary half-pay, Madras. Surgeon-Lieutenant-Colonel Bovill, Civil Surgeon of Darjeeling, is appointed to be Civil Surgeon of Murshidabad, but will continue to act as Civil Surgeon of Howrah. Surgeon-Major Drury, officiating Civil Surgeon of Chittagong, is confirmed in that appointment, vice Surgeon-Lieutenant-Colonel Lewtas, transferred. The services of Surgeon-Captain W. Henvey (Bengal) are replaced at the disposal of the Military Department on his return from furlough.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Major William Collingridge, M.D., to be Surgeon-Lieutenant-Colonel on increase of Establishment.

VOLUNTEER CORPS.

Rifle: 4th Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Lieutenant E. A. Malcolmson resigns his commission. 1st Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant L. A. Morgan, M.D., resigns his commission. 1st Volunteer Battalion the Hampshire Regiment: William Brooks Colquhoun, to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Durham Light Infantry: Surgeon-Major T. A. McCullagh to be Surgeon-Lieutenant-Colonel. 1st Dumbartonshire: Surgeon-Captain J. Wylie, M.B., resigns his commission.

THE VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the under-mentioned officers of the Volunteer Force:—*Home District: Rifle:* 2nd Volunteer Battalion the East Surrey Regiment: Surgeon-Major William Gandy. *North-Eastern District: Rifle:* 1st Volunteer Battalion the Lincolnshire Regiment: Captain and Honorary Major Frederic Riggall, Surgeon-Lieutenant-Colonel Henry Wright and Surgeon-Captain George May Lowe, M.D. *Scottish District: Rifle:* 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry: Surgeon-Lieutenant-Colonel David Cowie, M.B. 6th Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant-Colonel Robert Shand Turner, M.D.

MEDICAL HEROISM IN CUBA.

There seems to be no doubt that in many respects the Cubans have received cruel, not to say barbarous, treatment at the hands of their Spanish masters, but happily this grave charge is not of universal application. The medical officers of the Spanish army, as befits men practising the art of healing, have in many instances acted noble parts and at least one of their number has exhibited heroism of the very highest order. In the course of a sanguinary engagement with the insurgents Dr. Duran proceeded to the front line with the intention of affording aid to the Spanish soldiers who were falling rapidly under a hot fire; but scarcely had he reached the scene of action when he was struck by a Mauser bullet which shattered his knee-joint. In this piteous condition Dr. Duran managed, with the help of his orderlies, to bind up his own wound and then forthwith commenced a series of no fewer than twenty major operations on others, inclusive of reduction of protruding intestine with suture of abdominal opening, extraction of bullets in various situations, adjustment of compound fracture of the leg, &c. Many of Dr. Duran's colleagues have been killed in the course of this lamentable campaign and others have died from disease; while several more, having been unfortunate enough to fall into the hands of the insurgents who do not respect the Geneva convention, have undergone the most barbarous treatment. One of the latter, a young and promising surgeon, was taken prisoner and subsequently set at liberty, but not until both his hands had been severed at the wrists with a hatchet.

THE FRENCH ARMY MEDICAL SERVICE.

The Minister of War's Bill for the reorganisation of the French Army Medical Service, of which our Paris correspondent gave some details in a recent letter,[1] has been adopted by the Chamber of Deputies without discussion as an urgent measure. According to *La Semaine Médicale* the number of officers in each grade is as follows:—

	Old Cadre.	New Cadre.
Inspector-General	1	1
Inspectors	9	11
Principal Medical Officers, 1st class	45	45
" " " 2nd "	45	60
Surgeon-Majors, 1st class	320	340
" " 2nd "	480	500
Surgeons, 1st class	300	400
" 2nd "	100	50
Assistant Surgeons	—	50
Totals	1300	1457

THE WEST AFRICAN TROUBLE.

The mail-steamer *Accra*, which arrived at Liverpool on May 1st, brought some wounded officers who had been in the fighting at Sierra Leone, and among them Surgeon-Captain Scott, A.M.S. This officer, who had previously seen service with the Chitral relief expedition, is reported to have behaved with great gallantry whilst accompanying Major Norris's force in their march between Karene and Port Lokko. Surgeon-Captain Scott, after having been severely wounded in the thigh and elsewhere, ignoring his own injuries and sufferings, attended with the greatest devotion to the wounds of several natives of the company who had been shot in the same engagement.

OPERATIONS IN THE SOUDAN.

It is believed that the Anglo-Egyptian force will be strengthened by the addition of four British regiments before the final advance is made on Khartoum. It is not quite certain yet whether the advance will take place in August or October. In spite of the severe defeat which the Dervishes have received it is highly probable that the Khalifa's force will make a strong resistance at the last. The Anglo-Egyptian troops in the field and at Berber are healthy, but the heat is beginning to be great and, as might be expected, some cases of fever and dysentery have occurred.

MORTALITY IN THE NAVY AND ARMY.

Mr. James J. McLauchlan recently quoted some interesting statistics in a lecture which he delivered before the Institute of Actuaries. The conditions under which the sailor and soldier live are far more sanitary now than in the past, and it is not surprising to find that longevity in the services should have considerably improved within the last three decades. In 1865 over 11 deaths occurred in every 1000 men afloat, while ten years later the number fell to 6·8, in 1885 to 5·4, and in 1895 to 4·4. In the army the figures are not quite so satisfactory.

[1] THE LANCET, April 2nd, 1898, p. 966.

LEAN'S ROYAL NAVY LIST.

The April issue of this valuable publication revised up to March 25th is now ready and can be obtained from Messrs. Witherby and Co., 326, High Holborn and 4, Newman's-court, Cornhill. The publication is so well known and widely used that it would be superfluous to describe its contents. Suffice it to say that this almost encyclopædic work of reference on all official matters connected with the Royal Navy and the officers of that service and the Royal Marines has been brought up to date.

DEATHS IN THE SERVICES.

Brigade-Surgeon George Monorieff Govan, M.D. (retired), late Bengal Medical Service (3rd Goorkhas), at Almera, North-West Provinces, India, on April 1st, in his sixty-seventh year. He served in the Burmese War, 1852–53, including the capture of Rangoon and storming of the blockades of the Dragon Pagoda (medal and clasp), and in the Bhootan expedition, 1864–66, including the capture of Buxa and Tazagaon, attack on the Bala Stockade, &c. (clasp).

Correspondence.

"Audi alteram partem."

"THE DIPLOMA OF THE APOTHECARIES. SOCIETY."

To the Editors of THE LANCET.

SIRS,—I have been somewhat surprised that until the letter of "L.S.A." no correspondence has appeared in the leading medical paper with reference to the action of the General Medical Council and the L.S.A. qualification. It appears to me that—observing the personalities of this august body—it is the outcome of the not very remote action of the general practitioners themselves. They were called upon to elect to the Council a gentleman to safeguard and promote their own interests. Did they do so? Instead of electing a gentleman engaged directly in general practice, cognisant of its worries, cares, and responsibilities, they return a gentleman who, holding a high position in the scientific world, with absolutely nothing in common with the general practitioner and holding views of things appertaining to the profession peculiarly his own, feels called upon to show contempt for the Society of Apothecaries and its Licence. Mark what is the result: an unwarrantable attack on a gentleman holding the L.S.A. and who has passed a creditable examination in surgery, in medicine, and in midwifery, approved and sanctioned by the General Medical Council itself. I am not myself a L.S.A., but I respect all men who hold the diploma and if a gentleman so qualified is not to be styled a surgeon and a physician, what word must be coined to designate this Licentiate? But worse, far worse, is the unnecessary persecution of this properly qualified practitioner, who holding the degree of M.D. is not allowed by this almighty council of men to style himself "Doctor" because, forsooth, they refuse to register this degree, not being a British one.

What about the M.D. Brussels? What about the bastard M.D.—viz., the M.B.? Is a LL.D. or a D.D. holding the M.R.C.S. to be debarred from being addressed as "Doctor" because certain persons might be led to believe his title implied he was a doctor of medicine? If so let the general practitioners take steps to prevent certain of those who sit in high places in our profession who hold the F.R.C.S. Eng. and LL.D. (Hon. Caus.) from being addressed as and using the title of "Doctor." I am acquainted with a gentleman, a M.D., who is a practising barrister-at-law. As well might the Incorporated Law Society restrain him from using the title of "Doctor" implying (to some minds) that he is a doctor of law.

Evidently in this sudden accession of stimulation applied to the General Medical Council, the general practitioner is to be persecuted, whilst as your correspondent "L.S.A.", rightly states "the ignorant quack may practise with impunity"—and so may the prescribing chemist—and so

may certain gentlemen holding the M.D. of a British university who countenance canvassing touts and are sweated by one penny per week friendly societies. Truly the General Medical Council is a quaint body.

I am, Sirs, yours faithfully,

Mortimer-street, W., May 2nd, 1898. PERCY POPE, M.R.C.S.

"COLLAPSE FOLLOWING LAPAROTOMY."

To the Editors of THE LANCET.

SIRS,—In reference to the error in THE LANCET of April 23rd as to the amount of brandy injected intravenously, corrected by Dr. Bolton in THE LANCET of April 30th, the following case may be of interest, especially as it was due to Dr. Bolton's first note that we injected the larger quantity. An unmarried woman, aged twenty-three years, was admitted into this hospital on April 25th, under the care of Mr. Whipple, with a large, hard, solid tumour of the left ovary, sarcomatous in nature, and reaching as high as the umbilicus.

On April 26th an examination under chloroform was made and on the 28th the abdomen was opened in the middle line by Mr. Whipple, who removed the whole growth, though with great difficulty. The omentum and bowel were intimately connected with the tumour, the adhesions being extremely vascular, with omental veins as large as a No. 12 catheter, constantly requiring ligature. The growth was so adherent to the uterus and had so infiltrated the broad ligament that it was necessary to remove the uterus with the right appendages. The uterus was amputated at the internal os, flaps of peritoneum being raised from the fundus and sutured over the stump with Lembert's stitches. Finally, a secondary growth was removed from the omentum close to the great curvature of the stomach. After filling the abdominal cavity with warm, sterilised saline solution the wound was closed without drainage. The operation lasted two and three-quarter hours and at the end of the first hour the bleeding, which was very profuse, had so told upon the patient that her pulse was almost imperceptible at the wrist and at one time it was feared that she would not leave the table alive. The right basilic vein was therefore opened and 3 pints of saline solution (100° F.) with 4 oz. (*sic*) of brandy were injected. After a pint had been introduced the result was marked, the pulse becoming of good force and tension, the normal colour of the lips returned, and the eyes, which before were glazed and staring, resumed their natural appearance; the injection of the remaining 2 pints was continued during the rest of the operation, so that with the addition of 5 minims of strychnine hypodermically and a nutrient enema on leaving the table she had a temperature of 99·6°, her pulse was 84, and her respirations were 28. For the next few hours the temperature varied about 100°, the pulse was 140, and the respirations 34. Since then (now the fourth day) the temperature has been 98°, the pulse 86, and the respirations 20. She has had absolutely no pain, only once been sick, and apparently suffered not at all from shock. I have, I think, rarely seen a patient suffer less from an abdominal operation, and this, as the foregoing shows, was an exceedingly severe one, and certainly have never seen any abdominal patient after ordinary saline injection (of which we have had several lately) do so well.

My best thanks are due to Mr. Whipple for his kindness in permitting me to publish the case and he desires me to state that he is firmly convinced that the patient's excellent condition immediately after and since the operation was entirely due to the brandy.

I am, Sirs, yours faithfully,

J. DILL RUSSELL, B.S. Lond.,

Senior House Surgeon, South Devon and East Cornwall Hospital.

Plymouth, May 1st, 1898.

*** We have received a confirmatory letter from Mr. Whipple, and also a note from Mr. Dill Russell, informing us that only 3 ounces of brandy were ordered, but that the solution received by error an additional ounce of brandy. By a somewhat singular coincidence we find in a paper published in the *Practitioner* for May the following. The author, Dr. D. J. Leech, is writing on the treatment of bronchitis, and says: "I advised drachm doses of ipecacuanha wine every four hours. Next day I found the patient much relieved and charmed with the medicine, which had caused sickness, but not much. I found, however, that by mistake the wine had been administered in ounce doses."—ED. L.

"IMPORTANT VERDICT AS TO MEDICAL FEES IN HOSPITALS."

To the Editors of THE LANCET.

SIRS,—With reference to the case alluded to by you of Dr. Cranny *v* Mr. T. J. Lee for fees for surgical attendance[1] allow me to place before you the following letter which I received about 10 P.M. on the night of the occurrence. It is from the house surgeon of the hospital.

Jervis-street Hospital,
17 xi. 1896.

DEAR DR. CRANNY,—There is a gentleman of the name of Lee (Alexander and Co., Mary's Abbey) who has just come in here with a compound fracture of leg. He is most anxious to see you and asked me to send for you at once if you would be kind enough to come.

Yours, &c.,
MORE CARAHER."

From this letter, which, owing to the rules of evidence, was not allowed to be placed before the jury, it appears to me that I was justified in the position which I assumed, and which position was endorsed by the learned judge and by the jury—viz., that I was under the impression that I was specifically retained at the request of the defendant to take charge of his case. The law as laid down, and no doubt correctly, by the learned judge has decided otherwise. The important question remains as to whether a person of independent means suffering from an accident or injury, and being admitted to a hospital and being cared for and treated as the necessities of his case demanded (of which no question arises), but being in the rank of life capable of paying for surgical treatment, he should have a claim for the services of any hospital surgeon without paying for them because this surgeon is expected to attend the poor without fee or reward and because the patient has paid for his private ward a sum of 3 guineas a week to cover his maintenance and nursing. I submit that no hospital authority has the right to farm out the services of surgeons, nor, indeed, in my case do the managing committee of my hospital assert any such right. It would, in my opinion, be extremely detrimental to private practice were such a claim made. Need I add that had a plea of inability to pay been made nothing further would have been heard of the case. It will be a warning to the profession to safeguard themselves.

I am, Sirs, yours faithfully,

Merrion-square, Dublin, April 30th, 1898. JOHN J. CRANNY.

*** Dr. Cranny has enclosed a copy of the following letter from the defendant:—

[ENCLOSURE.]

Geo. Alexander and Co.
Telegraphic Address: Alexander and Co., Dublin.

2, 3, 4, and 5, Mary's Abbey, Dublin,
16 June, 1897.

Dear Dr. Cranny,—I do not know how to apologise to you for my neglect in not calling upon you to thank you for all your kindness to me and to settle my indebtedness. Please let me know amount and I shall send you cheque with sincere thankfulness. Trusting you will overlook delay, Believe me, yours truly,

(Signed) THOMAS J. LEE.

J. J. Cranny, Esq., M.D., 17, Merrion-square.

"A GRAVE PUBLIC DANGER."

To the Editors of THE LANCET.

SIRS,—With regard to the injury from combustion of a celluloid comb, reference to which has been made in your columns, I beg to say that the young lady was sitting on the hearthrug near the fire when she became suddenly aware that her head was on fire, and if it had not been for the presence of mind displayed by a friend who happened to be in the room the injuries must have been much more serious than they were. The actual injury was a burn of the third degree (Dupuytren's classification) over the right parietal region, surface extent 3½ × 1½ in., and there was considerable shock to the nervous system, which happily was soon overcome. I am glad you are taking up this matter, as I am sure ladies using these combs have no idea of the danger they are carrying in their heads.

I am, Sirs, yours faithfully,

Gravesend, April 23rd, 1898. C. J. W. PINCHING.

[1] THE LANCET, April 30th, 1898, p. 1222.

MEDICAL POLITICS.

To the Editors of THE LANCET.

SIRS,—All medical men must admire Mr. Victor Horsley's attempt to make registration the narrow way through which alone the right to practise for gain can be obtained. But if the right to sell drugs remains the privilege not only of the chemist but also of the man in the street, of what value is the assertion of the law as regards registration? The chemist can still prescribe *sub rosa*, and the quack can still blow his brazen trumpet in the market and the press. I fully sympathise with Mr. Horsley's effort, but these loopholes seem to me still open. These avenues to unqualified practice can never be wholly closed; perhaps it is not desirable that they should. A compromise is all that is possible and most practical legislation is compromise. If we were a prescribing instead of a dispensing profession it would no longer be the chemist's interest to evade the law; compulsory publication of the active ingredients of proprietary medicines would do much to lessen the evils of quackery. We no longer keep apothecaries' shops, but the spirit of trade, of cutting and underselling still exists; and if we take our stand as professional men, not as tradesmen, we must minimise that spirit.

I remain, Sirs, yours faithfully,

Loughborough, April 23rd, 1898. J. B. PIKE.

THE LIMITS OF PROFESSIONAL SECRECY.

To the Editors of THE LANCET.

SIRS,—I am anxious to know the law with regard to the divulgence of professional secrets, other than criminal, arising in the case of a servant in the employ of the payer of the fee. Should the servant have a disease (say drink or pregnancy) which would entail dismissal from service if known to the employer, is the medical man, paid by such employer, at liberty to divulge on inquiry by the employer such confidence of the servant? Can any damage be claimed in such a case by the servant so dismissed from the medical man who has caused dismissal by divulgence of professional secrets to the employer who is responsible for services to such servant? Is it a matter of contract between the employer (who pays for) and the attending practitioner? or is the monetary consideration overridden by the law of professional secrecy? I am, Sirs, yours truly,

Cheniston-gardens, W., April 26th, 1889. E. A. BARTON.

TINCTURA BELLADONNÆ B.P. 1898.

To the Editors of THE LANCET.

SIRS,—The increase in strength of this preparation is so marked that we think it desirable to call the attention of prescribers to the fact. It is now required to contain about 0·05 per cent. of alkaloid. The tincture prepared according to B.P. 1885 rarely contained more than 0·025 per cent. of alkaloid, so that for all practical purposes the new tincture is double the strength of the old, while the official dose remains almost the same. We hear from Messrs. Spottiswoode and Co., the publishers of the Pharmacopœia, that that work will not be obtainable till May 11th, although by its advertisement in the *Gazette* on Friday last it became binding on all dispensers. It would therefore be a great benefit if for the present prescribers would indicate by which Pharmacopœia they desire their prescriptions to be made up, as the above is not the only preparation of which the strength has been materially altered.

We are, Sirs, yours faithfully,

Oxford-street, W., May 3rd, 1898. JOHN BELL AND CO.

"A NEW OPERATION TABLE."

To the Editors of THE LANCET.

SIRS,—In your description of an operation table in THE LANCET of April 30th you state it is said to be the first table ever made whereon the patient can be placed in the Trendelenburg position without loss of heat. We venture to point out that this surmise is not correct as there are several operation tables of our manufacture in use at institutions in London and the provinces in which this provision is made, and one of these tables was on view during the whole of last summer in the Aseptic Operation Theatre at the Victorian Era Exhibition at Earl's-court. Trusting you will kindly insert this correction,

We are, Sirs, yours faithfully,

St. Thomas's-street, London, S.E., May 4th, 1898. DOWN BROS.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague in India.—Lessened Mortality in Bombay.—Outbreak at Kurrachee.

THE steady and marked decline in the number of plague deaths in Bombay almost day by day for the past three weeks has reassured the public mind and the almost complete relaxation of repressive sanitary measures has also contributed to a more contented state of the people. There is reason to believe that the number of deaths from other diseases than plague is considerably less than normal, so that except for the outbreak of a fresh epidemic of some other disease the average mortality may soon be anticipated. There are districts on the outskirts of the city where the disease is languidly spreading, but among the thickly populated quarters it is rapidly dying out.

The lesson to be learnt from these facts is that once an epidemic of plague has passed its point of highest intensity and has begun to show unmistakeable signs of decline it will not revive again, but will continue its course of abatement notwithstanding the abandonment of all sanitary precautions against its spread. The conditions for its survival and spread exist just as before, but the organisms of plague would seem to have what may be called a national life-history of which we know nothing, as well as an individual life-history about which we are only just beginning to collect a few facts. The native committees and other native organisations for detecting cases of plague do not seem to be more successful than their European predecessors. There still continue to be recorded daily about the same proportion of undetected cases of plague. Kurrachee has now become attacked—the totals to date being 77 cases and 42 deaths—and the town has been declared an infected port within the meaning of the Venice Convention. At Simla considerable opposition is being raised by the Hindus and Mohammedans regarding the proposed plague precautionary measures. The Hindus suggest that certain men of each sect should report when plague cases occur and that only then should the medical authorities act. House visitation and segregation are opposed. Should these suggestions be acquiesced in by the Government it is obvious that the sanitary measures will merely follow the plague and will not be ahead of it. Such a course has already proved in other places almost useless.

Arrangements are being made for a congress of the profession to be held in Bombay next December having for its chief object to consider the most appropriate means of dealing with plague epidemics in Indian cities, towns, and villages. What with the great improvement trust scheme and the reorganisation and elaboration of the health department, Bombay is actively preparing not only to wipe out its evil sanitary reputation but to establish an enlarged and beautified city.

April 15th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Sewage Treatment and the Local Government Board.

THE discussion as to the treatment of the Manchester sewage, adjourned from the previous meeting of the City Council, was resumed at an adjourned special meeting held on April 20th. One of the objections urged against the adoption of the "bacterial system" was that, unlike that of such a place as Sutton, the sewage of Manchester was destructive to bacterial life, being charged with the effluents from chemical and other works, and that therefore the system must fail. It was pointed out, however, that it had been tried for some years and had succeeded at Oldham, where the sewage was of much the same character as at Manchester, and further that the report of the chemist of the corporation, mentioned in my last letter, "had shown conclusively

that the sewage of Manchester was practically purified by the passage through the bacteria beds." An amendment to the resolution mentioned below was moved, but rejected, to defer all action till the report of the Royal Commission on the subject of sewage disposal had been received. But not only was delay advised; some wished the discarded culvert scheme to be revived, while others objected to the purchase of the 200 acres of land at present insisted on by the Local Government Board. The gist of the resolution adopted was that the recommendations of the rivers committee be adopted so far as they advised "the construction of bacteria beds upon 37 acres of land at the Davyhulme sewage works," and "the purchase of the necessary land for the aeration of the effluent after it has passed through the bacterial filter beds." The Local Government Board in accordance with ancient custom insist on the purchase of these 200 acres; but if as the result of further experience or of negotiations with the board the land should not be required for sewage purification it is believed that it will be a valuable asset to the corporation.

Proposed Extension of Monsall Hospital.

At the same meeting of the City Council a resolution was adopted in favour of seeking power to borrow £27,500 for the extension of Monsall Fever Hospital. The chairman of the sanitary committee explained that the extension was for the purpose of providing larger and better accommodation for nurses and servants and securing and laying out land for recreation and exercise. He said that no small-pox cases were to be taken to Monsall, but that in due time a scheme for a permanent small-pox hospital for the city would be laid before the Council.

Progress of Electric Lighting.

Mr. Alderman Higginbottom, chairman of the electricity committee of the City Council, brought forward at the same meeting the recommendation of the committee to apply to the Local Government Board for their sanction to the borrowing of the further sum of £150,000 for various extensions of the "electricity undertaking" of the corporation. The large scale on which this undertaking was first launched appeared to some to be rash and almost reckless, but the expectations of the committee have proved far too modest. Alderman Sir John Harwood said "it was ridiculous to come time after time for small sums"; he would have been in favour of £300,000, but he moved an amendment that £200,000 be asked. This was carried and is no doubt justified by the continuous and rapid development of the undertaking. The use of gas is also increasing instead of being lessened by its active competitor, as if the more artificial light the people have the more they want.

The Infirmary Board and the Spiritualists.

A matter was brought before the board of the Manchester Royal Infirmary on the 25th ult. which is outside the routine of their ordinary business. It was reported at a meeting of the house committee that a parade of the Spiritualists took place on the infirmary flags on the afternoon of Sunday, April 10th. Those responsible for the parade stated that permission had been given by the Watch Committee of the corporation. The house committee therefore decided to ask the town clerk of Manchester under what circumstances and conditions such permission was given as there had been no communication from the Watch Committee or the officials of the parade. We must fain hope that no serious consequences will ensue, but the question is evidently a grave one and cannot be answered offhand, for "the town clerk replied, stating that the matter would receive attention." At present no one seems any the worse from so many eccentrics having been collected together.

May 3rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Pathological Diagnosis Society of Liverpool.

THE first annual report of the Pathological Diagnosis Society of Liverpool, founded by Professor Boyce in May, 1897, has just been issued. During the last twelve months 179 medical practitioners have become members of the society, to whom over 500 reports on specimens examined have been sent. These reports chiefly dealt with the bacteriological examination of sputum and suspected diphtheria cases, the serum reaction for typhoid fever, and the examination of urinary deposits and of tumours. The report deals with directions for the selection and transmission of sputum, laying stress upon the advisability of sending the more solid portion of the expectorated material, unmixed with any fluid, which should be transmitted in a clean, wide-mouthed bottle. The sputum has been examined chiefly for the tubercle bacillus, which was found in about one-half the number of cases sent, the method used being the ordinary staining with carbol-fuchsine, followed by decolourisation in 25 per cent. acid. 77 cases of suspected diphtheria have been sent to the laboratory, of which 38 were returned as containing the Löffler bacillus, 23 as growths of other organisms, chiefly staphylococci and the pseudo-bacillus of Roux and Yersin, whilst in 16 cases growths were absent. Useful directions are given under the heading of Diphtheria as to the mode of obtaining and transmitting the material to be examined. In the case of tumours 47 specimens were sent to be examined, only a few of which presented features of special interest. In the matter of typhoid serum reaction 140 specimens were examined and reported upon; the results obtained were in accordance with those of other observers and were very satisfactory. Dr. S. R. Christophers, who for the last six months has been investigating the agglutinative action of various sera, has inserted in the report a short but interesting account of the serum diagnosis. About 70 specimens of urine were sent and reported upon. As regards the presence of the tubercle bacillus in urine, which is diagnostic of tuberculosis of the urinary tract, a difficulty in recognition consists in the fact that the smegma bacillus stains in the manner which is also characteristic of the tubercle bacillus. It is therefore desirable that urine for examination should be drawn off by means of a catheter. Inoculation experiments have also been made for the recognition of rabies, tuberculosis, and anthrax.

Ladies' Charity and Lying in Hospital.

Dr. Alexander Stookes has been appointed to the vacancy in the honorary hospital medical staff. Dr. Stookes had been for some years one of the district medical officers of the charity.

Death of James Mercer Johnson, M.D. St. And.

The death occurred, on April 22nd, of Dr. James Mercer Johnson at the age of sixty-eight years. Dr. Johnson retired from practice a few years ago owing to failing health. The deceased at one time had an extensive practice in Everton and for many years was attached to one of the volunteer corps in the capacity of surgeon. He was also a prominent Freemason and was much esteemed by his numerous friends and former patients. Dr. Johnson graduated as M.D. at the University of St. Andrew in 1862.

Extension of the St. Helen's Borough Sanatorium.

The additions recently made to the St. Helen's Borough Sanatorium at Peasley Cross were opened on April 28th by the mayor of St. Helen's. The sanatorium was first opened in 1882 and consisted of an old house containing seven rooms with an average number of patients of twelve per annum. Extensions have taken place since the year 1886. Upon the Council deciding that the hospital should be free the number of patients rapidly increased. Two large pavilions were erected in 1894, but even then the accommodation was found to be inadequate. A further enlargement was decided upon last year when the new buildings recently opened were directed to be built. The total cost of the extensions has been £6389 Altogether the sanatorium or fever hospital has cost £14,120.

Mersey Volunteer Infantry Brigade.

Brigade-Surgeon-Lieutenant-Colonel W. J. Fleetwood has been promoted to the position of senior medical officer of the Mersey Volunteer Brigade. Brigade-Surgeon-Lieutenant-Colonel Fleetwood is known in Liverpool as a most enthusiastic and industrious volunteer medical officer and his promotion has given much satisfaction to the men of all ranks in the service. He took an active interest in the ambulance work of the 4th V.B. the King's Regiment, his own corps, and also in the work of the bearer company of the Mersey Volunteer Infantry Brigade. He also possesses the volunteer decoration. His promotion is due to the retirement after a long course of service of Brigade-Surgeon-Lieutenant-Colonel T. M. Wills, V.D.

May 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

A New Hospital for Phthisical Patients.

ON April 30th a numerous company of ladies and gentlemen, including several prominent members of the medical profession in Glasgow, visited the new Consumption Hospital established by Mr. Quarrier near his Orphan Homes at Bridge of Weir, Renfrewshire. The hospital contains forty beds, none of which are on the ground floor. The majority of the sleeping rooms have only one bed, but there are eight with two beds each. Lodgment of dust is carefully guarded against, all the windows are double with the exception of those for the staff and those of the two convalescent rooms, and all the rooms have hollow walls with air cushions so as to maintain a uniform temperature at all times. The propulsion system is employed for ventilation, the walls of each room being pierced with apertures for the purpose. The sewage is treated by a putrefaction system of purification, the arrangements for which have been designed by Mr. Copland, C.E., acting in consultation with Dr. A. C. Munro, medical officer of health of Renfrewshire. After the inspection Sir William Gairdner, K.C.B., delivered an address, in which he referred in very complimentary terms to the work accomplished by Mr. Quarrier, who, in his reply, said that £25,000 had been spent and that £35,000 more was being asked for with a view to the erection of five additional buildings, whereupon they would have 200 beds. He did not want paying patients, but he did not mean to imply that he would refuse them. If the hospital succeeded there might be a special one built for paying patients.

May 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The late Dr. Samuel Gordon.

DR. SAMUEL GORDON, who died on April 29th, in his eighty-second year, for a long time held a very prominent place among Dublin physicians. His various hospital appointments included that of consulting physician to the Coombe Lying-in Hospital. He was an ex-President of the Royal College of Physicians of Ireland and of the Royal Academy of Medicine of Ireland and up to the beginning of the present year he was President of the Royal Zoological Society of Ireland. His published works consisted of lectures on fever and clinical reports contributed to the medical journals.

The New Asylum for County Londonderry.

Matters have almost reached a deadlock in reference to this asylum. It would appear that the architect of the Board of Control in November last estimated the cost of the new asylum, to accommodate 600 inmates, as £90,000. The governors increased the amount to £110,000, but at a special meeting held on April 26th a letter was read from the architect announcing that as the estimate for the builders was £118,341 further reductions had been made by means of which the cost had been reduced to £114,370; but if this was too much the architect suggested further revisions to bring the sum down to £112,677. It is proposed to construct the building of brick in a plain and substantial manner, heated by hot water circulating at low pressure, and lighted by electricity. The governors seemed very dissatisfied that the sum they had proposed in November had been exceeded and the whole matter will have to be delayed another month to give time to rescind their former resolution. So much delay has been occasioned that the matter may as well be allowed to remain until the Board of Control is dismissed and county councils are established.

The Medical Staff of the Belfast Workhouse.

At an inquest held in Belfast on April 27th in reference to a child who while very ill had been removed from the Union Infirmary one of the intern medical officers of that institution stated that four medical men were expected to attend to 1900 patients. In the convalescent ward there were 387 patients and it was the duty of one medical man to attend to 400 patients in the infirmary. The jury in their verdict attached no blame to the medical man as it was impossible for him to attend to 700 patients daily. They strongly condemned a system which permitted this and requested the coroner to bring the matter before the Local Government Board.

The Belfast Corporation (Hospitals) Bill.

At a meeting of the Belfast Corporation, held in committee on April 20th, the Town Clerk read a letter from the Roman Catholic Bishop of Down and Connor, suggesting that instead of making the grant of £5500 at first asked for on behalf of the Mater Infirmorum Hospital the corporation should insert a clause in the Bill undertaking to pay £150 per annum to that institution. After some discussion the following resolution was adopted:—

That as the corporation, when considering the application for the grant of a site for the Royal Victoria Hospital, believed that in acceding to the request they were acting in conformity with the unanimous wish of the ratepayers, and were granting a site for a general hospital that would not only be open for the reception of all sections of the community, but be governed and managed by the representatives of all sections, and subject to the control of the subscribers of all denominations, the corporation cannot see their way to depart from these broad lines and are of opinion that if the claim of the Mater Infirmorum Hospital were acceded to much stronger claims could, and no doubt would, be presented by the several other hospitals in Belfast.

The Bill (one of the objects of which is to allow the city corporation to give five or six acres of, the lunatic asylum ground within the city as a site for the New Royal Victoria Hospital) came up for second reading in the House of Commons on April 26th. A special whip had been sent out in its favour by all the members for the city of Belfast. The second reading was carried by a large majority—175—and the amendment to refer it to a hybrid committee was also defeated. It was a very great mistake that any religious dispute should have arisen in connexion with this new non-sectarian hospital and it has given great satisfaction in Belfast that the House of Commons declined to consider a hospital question in such a light.

Irish University Education.

At a recent meeting of the archbishops and bishops of the Roman Catholic Church in Ireland resolutions were passed in which it was announced that statements recently made that they had been conducting private negotiations with the Government in reference to the Irish University question were denied. They also requested the Irish Members of Parliament to oppose by every means in their power the estimates for the Queen's colleges until the Government pledge themselves to bring in a measure to satisfy the demands of Irish Catholics in the matter of university education.

Belfast Dispensary Medical Officers.

The Belfast Dispensary Committee at their meeting on May 2nd showed their appreciation of their medical officers by deciding that each of the dispensary medical practitioners should get a fortnight's holiday and that their locum tenentes should be paid by the board of guardians.

Health of Belfast.

The report presented at the monthly meeting of the city council (May 2nd) of the health of Belfast from March 20th to April 23rd shows that in this period there were 1138 births registered and 765 deaths. There were 114 deaths from zymotic disease, 113 from phthisis, and 198 from diseases of the respiratory organs. The death-rate (annual) from all causes was 26·2. The deaths from chest diseases are in this period shown to be steadily decreasing. The number of cases of typhoid fever and the deaths therefrom are still high. Scarlet fever, though of a mild type, is on the increase, and deaths from measles are becoming more numerous.

The North Infirmary, Cork: Resignation of the Honorary Treasurer.

At the annual meeting of subscribers to the Cork North Infirmary held to-day it was announced that Mr. P. J. Forde, the honorary treasurer, had signified his intention of resigning owing to ill-health. During the twenty-two years that Mr. Forde has been in office he discharged his onerous and responsible duties with great assiduity and zeal and took more than a parental interest in the welfare of this important charity. He was ever ready to gratefully recognise the important services rendered by the medical staff of the institution and successive generations of physicians and surgeons have a lively recollection of his unvarying urbanity and courtesy. They could always count on the honorary treasurer to assist them in keeping their hospital thoroughly abreast with the progress of medical

science. A gentleman of broad and sympathetic views Mr. Forde was instrumental in procuring many improvements for the comfort and welfare of the patients. All regret the cause of his resignation and it is generally felt that it will be very difficult to find a worthy successor.

Appointment of Assistant Medical Superintendent at the Cork Lunatic Asylum.

The governors of the Cork District Lunatic Asylum decided on appointing a fourth assistant medical superintendent. Dr. Ross and Dr. John Fitzgerald were candidates for the appointment and on two occasions received an equal number of votes. At a meeting held to-day Dr. Ross withdrew and Dr. Fitzgerald was elected.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Warty Growths on the Back of the Right Hand in the Tuberculous.

AT a recent meeting of the Hospitals Medical Society M. A. Béclère drew attention to the frequency of warty growths on the back of the right hand and also on the thumb and index finger of the same hand in patients suffering from pulmonary tuberculosis. Out of 24 cases under his care at the Tenon Hospital 4 exhibited these warts. In 1 case only were these growths on the left hand and that patient was a man left-handed from birth. A suggested explanation for the presence of the warts in the specified situation is the habit persons have of wiping the moustache and the lips with the back of the hand, especially with that portion of the metacarpus involving the thumb and index region. Infectious saliva is thus transferred to the hand and remains for a longer or shorter time on the skin, especially in the case of workmen who have not very frequent opportunities of washing their hands while at work. One of M. Béclère's patients was a mason who frequently wiped his mouth with the back of his hand to wipe off the dust from plaster, &c., which clung to his moustache. Another was troubled with itching of the upper lip and often rubbed it with the back of his thumb.

Functions of the Pituitary Body.

M. E. de Cyon laid before the Academy of Sciences at their meeting of April 5th the result of his researches on the functions of the pituitary body. He considered that from its situation the pituitary body is peculiarly prone to be affected by variations in pressure, whether that of the cerebro-spinal fluid or the blood. As a fact, excitation of this body manifests itself by a marked change in blood-pressure and by a considerable slowing of the beats of the heart, while at the same time the force of the heart-beat is considerably increased. This slowing of the heart-beat, which has been attributed up to now to the direct stimulation of the nerve-endings of the pneumogastric in the medulla, is only due as a fact to a reflex stimulation of these endings and the origin of the stimulus lies in the pituitary body. After ablation of the pituitary body occlusion of the abdominal aorta no longer brings about slowing of the heart-beat. After the pneumogastrics are excited the rate of the venous circulation in the thyroid body is increased to four times that of the normal rate and heavy pressure exerted on the pituitary body as a consequence brings into play the mechanism by which the thyroid body releases the brain from a dangerous influx of blood. Extracts of pituitary body injected into the veins of an animal produces identical effects of the heart and blood-pressure to those which are brought about by electrical or mechanical stimulation of that body. The active substance in the pituitary gland exercises upon the pneumogastrics an action analogous to that of iodothyrine.

On the Fatality of Koch's Bacillus when Mixed with Cow's Milk.

At the meeting of the Society of Biology held on April 23rd M. Sabrazès of Bordeaux showed that cow's milk very often contains the bacilli of Koch and plays a great part in the transmission of tuberculosis in animals to man. The important points to be noted are: (1) whether the bacillus of tuberculosis can form a colony in the milk under conditions of temperature and air-supply favourable to its growth; and (2) whether it preserves its virulence in this medium for a long time. Masses of a culture of the bacillus tuberculosis which had been grown in glycerinated bouillon were sown by M. Sabrazès upon the surface of a culture medium containing 250 c.c. of pure cow's milk such as is ordinarily exposed for sale two or three hours after milking. This milk was sterilised in an autoclave and after having been sown was placed in a stove with a temperature of 39° C. for two and a half months. At the end of this time no difference at all was evident between the milk used as a culture medium and a control specimen. The bacillus tuberculosis had not grown at all, neither had it brought about any notable change in its surroundings. The question remained of ascertaining whether the bacillus was still living in the milk. 1 c.c. of the tuberculous milk was therefore inoculated under the skin of a guinea-pig which died from tuberculosis 20 days afterwards. A second guinea-pig, inoculated with a potion of caseous gland taken from the first, also died from tuberculosis. M. Sabrazès considers that these experiments authorise him to say that although the bacillus of tubercle does not develop in milk even under favourable temperatures it will remain alive in this medium for a period of at least two and a half months and in all probability for a good deal longer.

May 3rd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

"Il Congresso pei Sordo-Muti" (Deaf-mutes).

THIS Congress has been the event of the week. Held in Milan and attended by delegates from all parts of Italy, including a large representation of physicians and surgeons, it attests the progress of which even a backward nationality is capable when philanthropy goes hand in hand with science and the healing art. Hitherto the fate of the deaf-mute, in continental Europe especially, has been a hard one. In antiquity he was put on the same level as the idiot simply because he lacked expression for the intelligence which was undoubtedly in him. S. Augustine stands alone among the Christian fathers in venturing to surmise that the deaf-mute can think and reason. But the man who first created a future for this "strangely-visited people" was Gerolamo Cardano, who boldly took up and defended the position that the reasoning faculty exists in the deaf-mute and that the difficulty he has to encounter is the finding of a channel other than that of sound through which the said faculty can have free course. To-day Italy can claim a foremost place among the countries which have succeeded in rehabilitating the victims of this too common affliction; she has, in fact, no fewer than forty-seven institutions, all of them able to afford living proof of the success with which the deaf-mute may be brought into touch and intercourse with his more favoured fellows—may indeed be converted into a bread-winner and into a useful, sometimes valuable, member of society. Statistics putting those results in evidence were adduced by the first of the experts in deaf-mute education to address the meeting—Professor Antonio Cipollini—and his discourse was followed by others full of interest, sometimes dramatic, sometimes touching in their tenour.

The Congress was noteworthy for the fusion of classes, creeds, and political parties represented at it, and for the enlightened unanimity—obtained after free and searching discussion—with which its practical resolutions were formulated and carried. To begin with, the hearts of all were touched by the object lessons in moral and intellectual reclamation submitted to them—reclamation in nearly every instance successful and secured after efforts on the teacher's part at once ingenious, kindly, and indefatigable. From the infant barely equal to emit a vowel-sound the ascent was very gradual, the next step being ability to pronounce a syllable, thereafter to articulate a word, then again a sentence, and so on till the series of illustrations culminated in the youth who, born deaf and dumb, was heard to express clearly and intelligibly his own thoughts and sentiments in a vote of thanks to the "Congressisti" for the humane impulse that had brought them together. In the discussions arising out of the agenda paper the Congress had the gratification of hearing the "sordo-muto redento" (the reclaimed deaf-mute) taking part opportunely and effectively; and this phenomenon—a real physiologico-educational triumph—seemed to put heart into the programme and to invest its details with an interest born of

hope and the assured prospect of final success. In harmony with this feeling attention was powerfully drawn and held by the *avvocato* Signor Natale Zucchi's report, "Sulla Condizione Giuridica del Sordo-Muto"—on his right, that is, to be treated like his normally-developed fellow citizens, having entire and perfect responsibility for his own acts. Tracing the legislative history of this "vexata quæstio" Signor Zucchi defined the present position of the deaf-mute as of one "*à priori inabilitato*" (disqualified). To acquire a "personalità civile" he must, according to Signor Zucchi, demand it at the risk of colliding with persons interested in leaving him in his condition of inferiority. Hence he finds himself in an abnormal situation—the law allowing him to marry, yet so treating him that "if the proscription of inability has not been removed" he cannot legitimise his own children, he cannot dispose of his possessions or give effect to his own wishes since he cannot dictate his last will and testament. Moreover, he cannot exercise political rights; nay, further, his inferiority in respect of "assistance publique" excludes him from the category of "cronici o gli inabili al lavoro" (chronic invalids and persons unfit for work). For the deaf-mute, added Signor Zucchi, instruction is not obligatory, although this would be peculiarly necessary for him since it cannot be given in the bosom of his family. Twenty years, concluded Signor Zucchi, have passed since the juridical and social reclamation of the deaf-mute and the "obbligatorietà dell' istruzione" (obligation to teach him) was first brought before the Italian legislature; but up till now nothing has been done for him in that quarter. The interesting discussion which ensued and flowed over into the following day led up to a unanimous resolution of which I give the text: "The Congress in behalf of Deaf-Mutes convened at Milan, considering in plenary assembly the report of the *avvocato*, Signor Natale Zucchi, on the juridical condition of deaf-mutes, accepts his proposals and expresses the wish that the Italian Legislature, in reparation for the neglect and abandonment in which it has left deaf-mutes before the law of social order and particularly before the law of obligatory instruction, should make urgent provision for the removal, in the domain of public and private right, of those restrictions and disqualifications which no longer apply to deaf-mutes who have learned *vivâ voce* to speak and who have been declared in that respect competent by the Commissione di Proscioglimento (Committee of Liberation) specially appointed." With this resolution the Congress rose, its members including Catholic priests and evangelical Protestants, freethinkers and agnostics, Conservatives, Radicals, and socialists—every shade, in fact, of creed and party—congratulating each other on good work harmoniously done, while all of them were touched (some even to tears) by the "sordo-muti redenti," drawn up 100 strong at the exit from the hall and going through a series of admirably executed evolutions, which ended with round after round of "evvivas" from lips congenitally sealed.

April 30th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The New Professor of Medicine.

THE Turkish Government lately asked for a professor of medicine from Germany. The German Emperor has now granted the necessary authorisation to Dr. Rider, professor at the Medical Faculty of Bonn, to fill a similar post at the Imperial Medical School of the Turkish capital. The newly appointed professor is to receive 30,000 francs a year. He is also to have an assistant, likewise a German, who is to receive a salary of 15,000 francs a year. Besides teaching in the school Dr. Rider is also charged to reorganise the medical school. He and his assistant will further have the duty of inspecting the military hospitals of this town.

The Plague.

The official bulletin issued by the Sanitary Administration here states that 46 cases of plague, of which 29 proved fatal, had occurred at Jiddah from March 22nd to April 11th. The Porte has already ordered precautionary measures and has despatched a medical commission to the plague-stricken districts of the Empire. News has reached this place of the arrival of the commission at Alexandria, where Dr. Bitter, Director of the Hygiene Institute of Cairo, has joined the Ottoman Commission. They are to make investigations concerning the bubonic plague.

April 15th.

BANQUET TO THE MEDICAL PROFESSION.

THE LORD MAYOR OF LONDON, Colonel H. D. Davies, M.P., gave a dinner to the medical profession on Wednesday evening last at the Mansion House. Invitations were issued "to meet the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, and other members of the medical profession," and as this was the first occasion upon which the hospitality of the Mansion House had been extended to the medical profession as such, a very large and distinguished company of guests assembled.

The following noblemen and gentlemen accepted the Lord Mayor's invitation:—Sir Samuel Wilks, F.R.S. (President of the Royal College of Physicians of London), Sir William MacCormac (President of the Royal College of Surgeons of England), the Marquis of Lansdowne, K.G. (Secretary of State for War), Lord Russell of Killowen, G.C.M.G. (Lord Chief Justice of England), Lord Shand, Sir William Turner, F.R.S. (President of the General Medical Council), Lord Lister (President of the Royal Society), the Right Hon. J. G. Talbot, M.P., Alderman Sir Whittaker Ellis, Bart., Professor Chiene (President of the Royal College of Surgeons of Edinburgh), Professor Clifford Allbutt, F.R.S., Sir George Duffey (President of the Royal College of Physicians of Ireland), Mr. T. McKinnon Wood (Chairman of the London County Council), Professor Burdon Sanderson, F.R.S., Dr. John Ogle, Alderman Sir H. E. Knight, Professor Sir T. Grainger Stewart, Sir Thomas Smith, Bart., Professor Sir George Stokes, Bart., F.R.S., Sir E. Maunde Thompson, K.C.B., Sir H. F. Norbury, K.C.B. (Director-General of the Medical Department of the Navy), the Master of the Society of Apothecaries (Dr. Griffith), Sir Alfred Garrod, F.R.S., Mr. Jonathan Hutchinson, F.R.S., Sir Charles Hall, K.C.M.G., Q.C., M.P. (Recorder of London), Sir Charles Cameron, Bart., M.P., Dr. Hermann Weber, Alderman Sir David Evans, K.C.M.G., Dr. Little (President of the Royal Academy of Medicine of Ireland), Mr. Thomas Bryant, Professor Michael Foster, F.R.S., Professor T. R. Fraser, F.R.S., Dr. Hill (Vice-Chancellor of the University of Cambridge), Sir Walter Foster, M.P., Sir Arthur Wells, Bart., Sir Dyce Duckworth, Sir J. R. Andrew Clark, Bart., Dr. H. C. Cameron (President of the Faculty of Physicians and Surgeons of Glasgow), the Rev. Sir Borrodaile Savory, Bart., Sir Benjamin Brodie, Bart., Mr. Christopher Heath, Surg.-General Jameson, C.B. (Director-General of the Army Medical Department), Surg.-Major-General Hooper, C.S.I. (President of India Medical Board), Professor Jebb, M.P., Mr. W. Christie, C.B., F.R.S. (Astronomer Royal), Sir W. Roberts, F.R.S., Sir W. Priestley, M.P., Sir Cameron Gull, Bart., M.P., Sir Arthur Watson, Bart., Q.C., Professor Annandale, Sir James Dick, K.C.B., Sir R. Douglas Powell, Bart., Sir Philip Smyly, Mr. Buckle, Sir Norman Lockyer, K.C.B., F.R.S., Dr. Farquharson, M.P., Sir William Broadbent, Bart., F.R.S., Sir Henry Thompson, Sir Francis Cruise, Dr. Pavy, F.R.S., Sir Paget Bowman, Bart., Dr. Playfair, Dr. Stevenson, Mr. H. Power, Dr. J. E. Pollock, Dr. Whipham, Mr. Timothy Holmes, Sir William Porter, Bart., Sir Halliday Macartney, K.C.M.G., Mr. Malcolm Morris, Sir J. Crichton Browne, F.R.S., Professor Dewar, F.R.S., Mr. Under-Sheriff Gardiner, Dr. Crosby, C.C., Colonel Eustace Burnaby, Mr. G. J. W. Wigzar, Mr. H. Gordon Davies, Mr. W. J. Soulsby, C.B., Sir Simeon Stuart, Bart., Dr. Sedgwick Saunders (Medical Officer of Health for the City), Mr. Under-Sheriff Halse, Mr. Alderman and Sheriff Green, Sir Henry Burdett, K.C.B., Sir G. S. Robertson, K.C.S.I., Professor Roberts-Austen, C.B., F.R.S., Deputy Inspector Woods, M.V.O., the Mayor of Hastings, Sir Felix Semon, Sir Thornley Stoker, Surgeon-Colonel Stevenson, Deputy Surgeon-General Tobin (Canadian Militia), Mr. W. A. Meredith, Dr. Macnaughten Jones, Dr. Cory, Mr. John Bowes, Professor Vivian Lewes, Mr. Noble Smith, Mr. C. N. Barton, Mr. Ryall, Dr. Foster MacGeagh, Dr. Ernest Clarke, Dr. Blandford, Dr. Symes Thompson, Professor Philipson, Dr. Long Fox, Dr. Glynn, Mr. O. E. Bulwer-Marsh, Dr. Claye Shaw, Dr. F. Warner, Dr. Dawson Williams, Mr. Shirley Murphy, Dr. J. G Glover, Mr. Howard Marsh, Mr. W. H. Bennett, Mr. Whitehead, Mr. Nicholson, Dr. Donald MacAlister, Professor Leech,

Dr. Theodore Williams, Dr. Bowles, Dr. Seaton, Dr. Jabez Thomas, Dr. Gilbart Smith, Dr. S. West, Mr. Butlin, Mr. Clinton Dent, Dr. W. Collingridge, Mr. C. Brook, Dr. Sheen, Dr. Orwin, Dr. G. D. Wilson, Dr. Cayley, Mr. Morgan, Dr. F. Taylor, Dr. Saundby, Mr. G. Brown, Dr. Savage, Dr. Oliver, Mr. Boyd, Mr. Critchett, Mr. Alfred Cooper, Mr. Burton (Warden Apothecaries' Society), Mr. Parker, Mr. Wheelhouse, Mr. Jessop, Dr. Dakin, Sir Peter Eade, Mr. Willett, Dr. Hensley, Dr. Dreschfeld, Dr. M. Skerritt, Dr. S. Mackenzie, Dr. Potter, Dr. Manson, Dr. Newsholme, Mr. Walsham, Mr. Pepper, Dr. Woodhead, Mr. T. Wakley, jun., Mr. Tomes, F.R.S., Sir R. M. Craven, Sir J. Sawyer, Mr. H. D. Erskine, Dr. Pye-Smith, F.R.S., Mr. J. Couper, Mr. Macnamara, Dr. W. J. Collins, L.C.C., Mr. Langdon, Mr. Davies-Colley, Dr. Henry Maudsley, Dr. Acland, Dr. Eddison, Dr. de H. Hall, Professor Ball, Mr. Clutton, Captain Sir A. Jephson, R.N., Mr. A. H. A. Morton, M.P., Dr. Clark, M.P., Mr. G. Lawson, Professor Stewart, F.R.S., Dr. Southey, Mr. W. Cheyne, F.R.S., Dr. Sansom, Dr. Barrs, Dr. Sharkey, Mr. C. Lucas, Professor E. H. Bennett, Mr. W. Anderson, Professor Mitchell Banks, Mr. Pitts, Sir W. Dalby, Dr. Ringer, F.R.S., Dr. E. Liveing, Mr. Teale, F.R.S., Mr. Howse, Dr. C. Bastian, F.R.S., Mr. E. Owen, Mr. Paget, Mr. H. Morris, Dr. Coupland, Dr. Black, Professor Redfern, Mr. Bond, Mr. Storr, Mr. Cotman, Mr. Gordon Brown, Sir W. Gowers, F.R.S., Dr. Church, Surgeon-Colonel Notter, Dr. Gee, Mr. Rose, Dr. Payne, Rev. Canon Edmonds, Mr. Croft, Professor Cuming, Dr. F. Roberts, Mr. Bloxam, Dr. Isambard Owen, Mr. Makins, Mr. Mayo Robson, Dr. Crawford Hayes, the Mayor of Ruthin (Dr. J. M. Hughes), Mr. Herbert Page, Dr. Burney Yeo, Dr. Lauder Brunton, F.R.S., Professor Halliburton, F.R.S., Dr. B. J. Anderson, C.I.E., Mr. Golding Bird, Dr. Luff, Mr. Barrow, Mr. Swanzy, Mr. Stonham, Mr. Felix Skene, Dr. Duffin, Mr. Barker, Dr. Ferrier, F.R.S., Dr. Norman Moore, Dr. Vintras, Dr. H. Green, Mr. Godlee, Dr. Poore, Professor McCall Anderson, Mr. Cadge, Dr. Champneys, Dr. Abercrombie, Dr. Tirard, Dr. Eustace Smith, Mr. McCarthy, Mr. Pollard, Mr. Spencer, Mr. Bennett May, Mr. Fairbank, Dr. W. Duncan, Dr. Barlow, Dr. Cavafy, Mr. Victor Horsley, F.R.S., Dr. Ewart, Dr. Ord, Dr. Goodhart, Dr. Curnow, Dr. Mapother, Mr. Treves, Professor Macewen, F.R.S., Mr. Tweedy, Mr. Barling, Dr. Manby, Dr. W. S. A. Griffith, Mr. Knowsley Thornton, Dr. Allchin, Fleet-Surgeon Mahon, C.B., Mr. George Cowell, Dr. Lees, Dr. Galabin, Dr. Charlewood Turner, Professor Corfield, Dr. Brodie, Mr. Pick, Mr. Pearce Gould, Dr. Arnison, Mr. Pye-Smith, Mr. Vincent Jackson, Dr. Clement Godson, Dr. Lediard, the Mayor of Henley (Mr. J. Lidderdale), the Mayor of Preston (Mr. J. E. Dunn), the Mayor of Devizes, Dr. Herman, Dr. Fowler, Dr. Spencer, Dr. Hollis, Professor Greenfield, F.R.S., Mr Haward, Dr. Page, Mr. Cross, Mr. Tindall, Mr. Cripps, Mr. Welland Mackenzie, Dr. R. Barlow, Dr. S. S. Sprigge, Mr. F. G. Hallett, Mr. Wherry, Professor Thomson, Dr. Ward Cousins, Mr. Swain, Mr. Bankart, Mr. Sibert Cowell, Dr. J. W. Fry, Mr. G. Stoker, Mr. Sheriff Dewar, Professor Bradbury, the Mayor of Cheltenham (Mr. R. Rogers), the Mayor of Carnarvon (Dr. R. Parry), the Mayor of Bootle (Dr. J. McMurray), Deputy Inspector-General Stanistreet, R.N., Sir H. T. Wood (Secretary of Society of Arts), Dr. Buzzard, Mr. Reginald Harrison, Dr. Donkin, Dr. Ernest White, Dr. Rutherford, Dr. Outterson Wood, Mr. A. W. Prichard, Mr. Eddowes, Mr. O. C. Maurice.

Dinner over and grace having been said, the loving-cup was passed round, and the Lord Mayor bade his guests a hearty welcome.

The LORD MAYOR, in proposing the health of Her Majesty, said: We are all glad to welcome back our beloved Queen to her own country. We are delighted to know that she has returned in such good health; may that good health long continue. I give you "The Health of the Queen," and may God bless her.

In proposing the toast "The Prince and Princess of Wales and the other Members of the Royal Family," the LORD MAYOR said: We all know the deep interest which every member of the Royal Family takes in the medical profession and the practical sympathy which they show in looking after the hospitals of London. We know how deeply they are interested in the welfare of the people and we are always delighted to greet them in the City. I ask you to drink to the health of the Prince and Princess of Wales and the other members of the Royal Family.

Lord RUSSELL of KILLOWEN, G.C.M.G., Lord Chief Justice of England, proposed the toast of "The Navy, Army, and Reserve Forces." He said: I think there is no section of the community that does not recognise the necessity for an adequate executive force by land and by sea. Differences of opinion indeed exist as to what is an adequate force, and those differences of opinion have been the cause of endless perplexities to successive Chancellors of the Exchequer and Secretaries of State for War. I think also that every section of the community agrees in this—that while it is necessary, looking to the greatly diversified and widely extended interests of this Empire, that there should be such adequate forces, yet the consensus of opinion is that such forces shall be forces of defence, not of defiance, forces which shall guarantee the peaceful exercise of our rights and not forces conceived or directed to purposes of aggression or of conquest. One thing we may truly say at all times of our army and navy: although frequently tried under circumstances of great difficulty they have never been found wanting when called upon to discharge their duty. Recent examples of this are before us both in India and in Egypt. I say nothing of the policy of the campaigns, but we are all entitled and glad to be able to recognise in the conduct of the officers and of the men the presence of fortitude, bravery, and endurance—characteristics which have always marked our soldiers. There is in connexion with those campaigns one circumstance which cannot but be regarded as most gratifying—namely, that the same qualities which have marked our home-bred soldiers have been manifest in the native forces both in India and in Egypt. With this toast two distinguished names are coupled. In respect of the navy there is an appropriateness peculiar to this occasion in coupling with that part of the toast the name of Sir Henry Norbury, the Director-General of the Medical Department of the Navy. There is a peculiar appropriateness on this occasion because, in the first place, he is a distinguished naval officer, and because it is relevant to this occasion to observe the great benefits that the distinguished profession which you, my Lord Mayor, have honoured and which has honoured you by its presence here to-night—the great benefits, I say, and distinguished services that this body has rendered in mitigating the horrors of war; I refer not merely to the qualities which characterise the medical profession, but the fact that in proportion to their numbers they show the largest number of any of Her Majesty's subjects who have received the Victoria Cross. Coupled with the part of the toast which relates to the army and reserve forces I have to mention the name of Lord Lansdowne, whose remarkable services to the Crown, first as Governor-General of Canada and afterwards as Governor-General of India, command the gratitude of the nation; and I am sure I am voicing your opinion and general public opinion when I say that the country has every confidence in the wisdom, caution, and administrative ability of the Secretary of State for War.

In responding Sir HENRY NORBURY said: It gives me very great pleasure to respond to this toast in the name of the officers and men of the Royal Navy, and I thank you most sincerely for the kind way in which you have received the toast. The navy is a service which, though always popular, is unable to attract the attention of the public because from its very nature it is unable to make the popular displays that the sister service can so readily do—except on occasions such as the Diamond Jubilee when people invaded Portsmouth to witness the naval review. At no time in our history has the navy been in a more efficient condition than it is now, not even in the time of that celebrated naval hero of whom as Englishmen we are all so proud, Nelson. I could not wish a more honourable or, I might say, pleasurable career for any man than one in the service of the navy. In the name of that service I thank you, my Lord Mayor, for the honour which you have bestowed upon us in asking us to accept your hospitality at the Mansion House this evening.

Responding on behalf of the Army Lord LANSDOWNE said: I see immediately before me the Director-General of the Army Medical Department and I cannot help feeling that on this occasion the duty which has been cast upon me might perhaps have been more appropriately placed in his hands. I have to thank you for the kind manner in which this toast has been received, and I am sure that the generous words of the Lord Chief Justice will be valued by all who are serving Her Majesty in the army and by all the friends of that service. It is said sometimes that in this country we are apt

to disparage our own institutions, and this applies sometimes perhaps when we are talking about the army; but it will scarcely be disputed that in the two campaigns which the Lord Chief Justice referred to British soldiers have shown that they are not unworthy to uphold the great traditions which belong to the British army. I think we must all of us have read with pride the farewell words of Sir William Lockhart, published in to-day's papers, when taking leave of the Tirah field forces. Both these campaigns had in them this feature—that British soldiers were serving under the same flag with men of races other than their own. The admirable performances of these native troops, their discipline and soldier-like qualities, may be without exaggeration to a great extent traced to the training which they have received from British officers. While we have in the British army leaders of men like Sir William Lockhart and Sir Herbert Kitchener—while such leaders are training up the younger race of officers to follow them, we need not despair of the British army. These campaigns are useful because they not only call attention to our strong points but also to our weak ones, and I am told that the Egyptian campaign has this one weak point which I ought not to ignore. I refer to the matter of the army boot. I am not going to admit that the army boot is a bad boot. I believe that it is a thoroughly serviceable article, but it appears that it does not resist the insidious effect of desert sands. In saying a word about the boots I must say a word about the wearers. General Gatacre in the march of his brigade to the front covered a distance of no less than 142 miles in five days, an average of over 28 miles a day. That as a feat of endurance, I think, is something for a British soldier to be proud of. In the future I hope we shall be able to discover a boot which even General Gatacre and the Egyptian desert will not be able to wear out. The army owes a very great debt to the profession you are honouring this evening. In peace the profession teaches us how to combat the diseases and the climatic influences to which in our ever-increasing Empire the British troops are exposed. When peace is broken medical men teach us how to mitigate the barbarity of warfare. Engines of destruction are now used more terrible in their effects and more deadly wounds can be inflicted in seconds now than in hours in times past. It is the medical profession which teaches us how to correct the effects of our own ruthlessness, and if we had to choose between the credit to the man who, say, invented a new Dum-Dum bullet and the credit to him who showed us how to extract it and save the shattered limb I do not think we should be long in deciding. I am using no idle phrase when I say that the army is proud that it contains a number of officers who belong to the medical profession, but who are none the less soldiers in the fullest sense of the word, wearing the Queen's uniform, holding her commission, ready to take their share—aye, and more than their share of the risks and hardships of warfare. We are determined that there shall be no failure either in theory or in practice to treat them with the respect to which they are entitled. It has been to me a source of very great regret that there have been of late years signs of a feeling of estrangement between the army and the medical profession which has been outwardly expressed by the abstention of candidates for commissions. In such cases it is, perhaps, not unfair to assume that there may have been faults on both sides. We on our side are determined that you shall have no cause to complain of us. In several minor matters to which I will not refer upon an occasion like this we have already shown our determination to meet you in a reasonable spirit. We are now about to deal with the large question in which I know the profession takes a deep interest—the question of the status and rank of the medical officers in the army. I have heard it said, Is not the title of "Doctor" or "Surgeon" a title by itself which anyone might be proud to wear? But in the army rank means a great deal. It is the outward and visible sign of that authority and consideration with which the place of a man is clearly defined and designated, and it is necessary in the military profession that a man should have a proper military stamp. Let me say in half-a-dozen words how it is that we intend to deal with this question. We have made in former years various attempts to solve this question of titles by means of ingenious expedients, but the results have not been very satisfactory. In some cases we have, I think, invented titles which for cumbrousness and cacophony would be hard to beat. We now propose that the Army Medical Staff and the Army Medical Corps should be formed into one corps. The titles used shall be the simple, short, intelligible titles to which we are all accustomed. We propose to give the corps military titles up to and inclusive of the rank of Colonel. I have received some forcible hints that our scheme will be unsuccessful unless we proceed to the rank of General. But we in future intend to limit the rank of General to a very restricted number of officers, all of whom will be required to hold certain specific appointments carrying with them general command in the army and they will be required to command troops, if necessary, in the field. I feel quite sure that it is not intended that any departmental officers shall be given the rank of General under this scheme. Her Majesty the Queen, whose goodwill towards the profession is well known, has signified her pleasure that the new corps shall be called the Royal Army Medical Corps. I cannot help hoping, my Lord Mayor, that your distinguished guests and their friends will give us credit for having made these proposals in a fair and reasonable spirit and that we shall find that they on their side will spare no pains to induce the best and most prominent recruits in their profession to join the Royal Medical Corps. I am sure that we must all desire to see improvement in the British army and that there may be found serving with it members of the medical profession who, by their ability and standing in their profession, are in every way worthy of those whom you, my Lord Mayor, are honouring this evening.

The LORD MAYOR: It now becomes my pleasing duty to propose the toast of "The Medical Profession." I feel a peculiar pleasure in proposing that toast because I think that this is the first occasion on which it has been proposed within these walls. I have heard various complaints from members of the medical profession serving in the army, but I little thought that this banquet would have been the medium of bringing forth such a satisfactory statement as that just made by the Noble Marquis the Secretary of State for War. We must admit that that statement is most satisfactory, and not only to those connected with the army. I am delighted to welcome you here to-night in the name of the citizens of London. I welcome you for more reasons than one. In the first place I welcome you because for many generations past you have been intimately associated with the City of London. I believe that the Royal College of Physicians commenced in the City of London in 1518. The Royal College of Surgeons was intimately associated with one of our ancient City guilds—I refer to the Barber-Surgeons Company. There is another company connected with your profession, also one of the livery companies, which has its residence in the City of London at the present time, and we members of the Corporation welcome you heartily as having some connexion with us both in times past and at the present time. But I welcome you on other grounds. I know the vast amount of good which you do to suffering humanity, and when I speak of suffering humanity I do not refer to it in the sense that you look to the comfort and health of the ordinary patient, but rather mean that you devote much of your valuable time to the amelioration of the sufferings of those poor creatures who are unable to help themselves. I see the names of those distinguished physicians and surgeons who devote their time to hospital work and know the immense amount of good they do and how instructive their work is also. They, as Lord Lansdowne has told us, train the young to take their places and we citizens are deeply grateful for the vast amount of good which is thus conferred upon poor humanity. I will not, my lords and gentlemen, occupy your time by making a longer speech. I am delighted to welcome you here to-night and to meet my two distinguished guests, the President of the Royal College of Physicians of London and the President of the Royal College of Surgeons of England. Every man present to-night is a distinguished guest. We welcome you all; we trust that we may see you again—not medically, but hospitably. I welcome you as Lord Mayor of the chief city in the world, the healthiest city in the world, not rendered altogether healthy by the assistance which you give us, but by the joint assistance of the Corporation of London and the medical profession. I give you the toast which I ask you to drink standing—"The Medical Profession," coupled with the names of my distinguished guests, Sir Samuel Wilks and Sir William Mac Cormac.

Sir SAMUEL WILKS (President of the Royal College of Physicians of London) said: I thank you very much for your very kind words about myself and my profession,

but if we had only heard the speech of the Marquis of Lansdowne we should have been satisfied because it may afford a good solution of a question which has so long been before us. But the meeting here to-night is unique, and, therefore, in spite of what has been said by my neighbour, I consider that what I may have to say is really the toast of the evening. I cannot pretend to interpret the minds or opinions of the most illustrious and most learned men of my profession who are gathered here to-night from all parts of Great Britain, but I am quite sure that there is one sentiment that animates them all and that is a feeling of gratitude to you, my Lord Mayor, for having given us this token of your recognition. As you have said, this is the first time that a banquet has been given to the medical profession at the Mansion House. There may have been cases, such as congresses, when many distinguished foreigners have been present in London and when the *élite* of the profession have been joined with them, but in ordinary times of quiet without any exciting cause, to use a medical expression, you, my lord, have cast a kindly eye over us and cast your ægis over the whole profession. You have taken a new departure. This may have come about for many reasons. Nowadays there is a closer connexion between the corporations and the sanitary authorities. Medical men no longer give their whole time to the individual patient in a private capacity, but have regard for the masses and, with the motto that prevention is better than cure, the doctors have become the guardians of the public health. A good example of this was seen the other day during that frightful epidemic of typhoid fever. But although we approach one another more closely now, for a long time there has been a separation. It was not always so. As you have said, my lord, there was a time when the two Colleges were City companies and at that time they were under the jurisdiction of the City and of the Lord Mayor; the same, I believe, applied to the other cities of Dublin and Edinburgh. The Physicians and Surgeons existed nearly 500 years ago as distinct companies in the time of Henry VI. and at that time they were closely connected with the Corporation of London and I believe they had to get their Licence from the Lord Mayor. The Lord Mayor of that time had a supervision over the instruments of the Surgeons and also over another class of persons connected with the Surgeons whose names I will not mention, although the Lord Mayor has done so. One reads in books how often they had to fine these Members of the College in sums of 6*s.* 8*d.* and 3*s.* 4*d.* for shaving polls and trimming beards on a Sunday. Subsequently came the Charter of the College of Physicians which we obey at the present time, and twenty years after that came the Charter given by Henry VIII. to the Surgeons. The celebrated picture by Holbein hangs in a hall close by. In that picture the King is presenting the Charter to the Surgeons. On his right hand are the physicians, Dr. Chambers and Sir William Butts. Previously to this time I believe the two Colleges held an examination similar to the conjoint scheme at the present day. The men who founded the two Colleges were men of the highest worth and integrity. One of these great men was Caldwell, who was instrumental in founding the Lumleian Lectures, and he laid down a code of ethics which could not be surpassed. Then there was Vycary, who held that a surgeon should be as secret as any confessor and also said that it is meet that chirurgeons should love one another. After this time they gradually ceased their association with the City and although they remained in the neighbourhood some time they gradually went westward. The Surgeons lingered towards the City a long time, as it had a great interest in, and was very much associated with, another institution in the City—I mean Newgate. It is pleasing to see that a new *rapprochement* is gradually taking place amongst us not only for the reason I have given. But the City of London and all the Guilds belonging to us have made an approach of late years to all the seats of learning. Benevolence and hospitality have always been characteristic of the City of London and the Guilds. Now they are adding to these qualities by devoting their attention to matters of learning. I need say nothing about Guildhall, where there is a splendid library, museum, annual picture exhibition, &c.; but, beside all that, they have done much for science and learning, and in our own profession we have especially to thank them for the help they have given to the advancement of scientific medicine. The City have given great assistance in the study of bacteriology. The future citizens of London will be proud of the part taken by the City of London and its Guilds in the scientific work of the closing years of the nineteenth century. As a crowning act you have called us here to-night in person and in the name of those here assembled I thank you most heartily.

Sir WILLIAM MACCORMAC (President of the Royal College of Surgeons of England) said: It is now my duty, however imperfectly I may be able to discharge it, to convey to your lordship on behalf of my surgical brethren and myself our most cordial appreciation of the honour you have done us and how gladly we accept the compliment you have been good enough to pay our profession in thus inviting us to this banquet. We are very proud of our profession and of the great strides it has made in recent years. I think we have just reason to be proud of it, for never before has our profession occupied so large a place in the State, never previously has it been able to accompany so large a measure of good for the community. And this, I think, is fully recognised, and by no one, I am sure all present will agree, has it been more gracefully or handsomely recognised than on this memorable occasion by the Lord Mayor of London. Speaking for surgery it is difficult for anyone not in immediate contact with the work to realise the immense progress which has taken place in surgery in the last few decades. It is astounding—to me personally it is a source of never-ceasing wonder and admiration—that older surgeons used to regard an operation as a stigma on surgery—a confession of failure to cure by other and less radical methods. From time to time we were assured by great masters of our craft that surgery had reached such a pitch of perfection that no further improvement was possible, but events have constantly falsified this prediction, and I believe there is no finality in surgery any more than in other branches of science. And assuredly operations are no longer a stigma. Large classes of surgical cases are now capable of not only relief but cure by operations which never before came within the range of practical surgery. Many with otherwise fatal ailments may be absolutely restored to health; many with crippling conditions of different kinds can be restored to full activity. Two great factors have enormously contributed to this end. One the blessed discovery of anæsthesia whereby the ghastly terrors of an operation are dispelled and many operations otherwise impossible can be performed. The other and not less beneficent discovery is the antiseptic treatment of wounds, which has practically removed the risks and sufferings formerly attendant on operations. The author of this glorious gift to humanity is amongst us to-night. Surgeons and surgery throughout the civilised world owe to Lister a debt very inadequately acknowledged by our affectionate admiration of the man whose patient insistence, both by observation and experiment, clear perception, and bold scientific induction have realised for him a name and fame that shall never perish. My Lord Mayor, the presence amongst us of the noble Marquis the Secretary of State for War induces me to say a word in regard to the Medical Department of our army. No confidential communication on this subject has been made by anyone to me and therefore I betray no confidence when I say that I am sure the members of the profession outside the army and those within its ranks are grateful for what the noble Marquis has done for those who thus serve their country, and my lord, have served it well, in the Medical Department of the army. Lord Lansdowne is responsible for the affairs of the whole army, yet I tell no secret when I say that the affairs of its medical department must of late have occupied a large share of his attention. He has dealt with these matters in a most sympathetic, generous, and I would add most wise and statesmanlike spirit. He has granted reforms, revolutionary changes almost, in the department, in spite of very strenuous and persistent opposition on the part of some who we may suppose do not belong to it. He has agreed to grant the two great wishes which have been pressed upon him—army rank and the formation of an army medical corps. A comparatively small question about the titles of surgeon-generals has also, I think, been solved; and all this should, I consider, give great and general satisfaction. Very fitly it is but right and fair to judge a man by what he succeeds in accomplishing, and Lord Lansdowne has accomplished for the Army Medical Department what they have very earnestly desired, and has done very much it may be hoped to restore

its former prestige, and it will be restored if all concerned work loyally to obtain it. A very celebrated Scotch surgeon, John Bell, writing at the beginning of this century, when all Europe was at war and the qualities of a military surgeon could be more justly appreciated than in time of prolonged peace, says that he has been accustomed to regard the public service of the State as a great school of practical science affording opportunities which more than compensate for the hardships and dangers of that way of life. The situation of a military surgeon he considers more important than that of any other. While he is yet a young man he has the safety of thousands committed to him in unhealthy climates and in the midst of dangers. He has to act alone and unassisted in cases where prompt decision and perfect knowledge are required and duties difficult in all times are often to be performed amidst the hurry, confusion, and cries of battle. He forms the highest estimate of the qualities, both personal and professional, that a military surgeon should possess, as it is to him that his fellow soldiers look in moments of distress. It is remarkable how many distinguished men in our profession have served their country in the wars. Many of the foremost men in France, in Germany, and in England have done so. There are some in this room now who have thus greatly distinguished themselves, and it has always been so. In the history of the City of London one might recall the names of many. The Father of English Surgery, Richard Wiseman, surgeon to King Charles I. and Serjeant-Surgeon to King Charles II., had an eventful career during the Civil War. He was taken prisoner after the Battle of Worcester and again while practising his profession as a surgeon in the Old Bailey at the sign of the King's Head he was taken to the Tower and nearly lost his own head during the Commonwealth. About the same time John Woodhall, a surgeon at St. Bartholomew's Hospital, Surgeon-General to the East India Company, also a celebrated surgeon in this old City of London, who had served both in the army and in the navy, dedicates his curious work on surgery and the duties of the surgeon's mate to the "King's most excellent Majestie" Charles I. and also to the Right Hon. Sir Morris Abbot, Lord Mayior. "Your poor subject," he says, "has presumed to prostrate at the feet of your sacred majestie these his unworthy works in surgerie which contain in them the methods and scope of the military surgeon's chest with the 'viaticum' or pathway to the chest with all the necessary appurtenances which are useful in surgery for the warres either by sea or land." Woodhall speaks of himself as an ancient master of the mysterie of Barber Surgeons, an old City company which became transformed in lapse of time, let us hope improved, into the Royal College of Surgeons, while the Apothecaries, who did so much in their time for the profession of this country, and still do so, continue as one of the City companies. So there are points of contact between our profession and the City of London. And now, my lord, I would add a word as to one aspect of the great Corporation over which you so worthily preside, and that is its never-failing benevolence and charity. It is shown in the part, more immediately concerning us, that you and the Corporation take in the government of the great charities of the City of London. In your corporate capacity you are Governors of the Royal Foundations of St. Bartholomew, of St. Thomas, and of Bethlem, and also of Guy's Hospital. These institutions amongst many others have had the closest connexion with the City of London and owe much to its influence both in the past and in the present. To you, then, my Lord Mayor, as grand almoner of the never-failing and unstinting charity of this great city, of which many amongst us are administrators—as Chief Magistrate of this the greatest city of our empire and of the world, I return, on my own behalf and on that of the surgeons of the United Kingdom, our most sincere and appreciative acknowledgments for the honour you have this day done to our profession.

Sir WILLIAM TURNER (President of the General Medical Council) said: My duty is a very responsible one—namely, to propose the toast of "The Houses of Lords and Commons." I have been present at festive gatherings where the speaker whose duty it was to propose the House of Lords proposed it in an apologetic manner. I am sure, my Lord Mayor, that in this city and in this hall such an apologetic manner would be entirely out of place. The City of London has had ample opportunities of knowing what the House of Lords is—how eminent it is, how honourable is its antiquity, how illustrous are its traditions and how representative it is of such of the great historic families of the United Kingdom as still remain with us. But the House of Lords would not have retained the esteem of the citizens of this country if it had rested solely upon its great families. It is constantly receiving new acquisitions, acquisitions from without. Men are brought into it who have rendered great services to their native country, either in the public services or in the professions. Some of the professions have been in this respect more highly favoured than others. The law has furnished many additions to the House of Lords (we have here this evening one of the most illustrious representatives of the profession of the law) but it has been an extremely difficult matter for the profession of medicine to obtain an entry into the House of Lords. We have heard that it has been a very difficult matter for the medical profession as a profession to obtain an entry into this Mansion House, and we thank you, my Lord Mayor, for having accorded us this entry this evening. In the selection of Lord Lister for the Upper Chamber we all felt that our profession was honoured and that at last justice had been done to it, and from this point of view—that Joseph Lister represented not only the practitioner but the science of his profession; he represents the great fundamental principles of our profession and it gives me the greatest pleasure of associating with this toast the name of Lord Lister. But I haveto ask you also to drink the health of the House of Commons, a place not so difficult of access as the House of Lords for the medical profession. There are many members of the House of Commons present to-night and we all feel grateful to them for the work they do in connexion with matters pertaining to the profession, matters chiefly of public health. Questions are continually arising in which the special knowledge of the medical practitioner does great service in matters of legislation, such, for instance, as the subjects of vaccination and public health. I have been asked to couple with this toast the name of one who has done excellent service for the public from a professional point of view, that of Sir Charles Cameron, and I ask you to drink to the House of Lords coupled with the name of Lord Lister and to the House of Commons coupled with the name of Sir Charles Cameron.

Lord LISTER said: I feel that it is exceedingly inappropriate that this toast should be responded to by so recent and humble a member of the House of Lords as myself; yet as a member of the profession which has been so uniquely honoured by you, my Lord Mayor, this evening, I rejoice in the privilege of returning to you our most cordial thanks; and if I were to speak the sentiments of my heart they would be that whatever the shortcomings of ourselves individually may be our profession is that of the very highest nobility. At this late hour of the evening I can but express my unbounded satisfaction to the Marquis of Lansdowne for the statement which he has made in regard to the Army Medical Staff. He has cleared the way and in the future the army will be served by the best elements of our profession.

Sir CHARLES CAMERON said: Lord Lister is one of the greatest members in the House of Lords although he has alluded to himself as "humble." As for the House of Commons the policy laid down by Beaconsfield, *Sanitas, sanitatum, omnia sanitas*, has become more and more engrafted upon the policy of the people's house. In the name of the House of Commons I thank you heartily for the manner in which Sir William Turner has proposed the toast and the way in which it has been received by you.

Sir GEORGE DUFFEY proposed "The Health of the Right Hon. the Lord Mayor."

In his reply the LORD MAYOR said: It is indeed gratifying to me to find that my name should receive such a cordial reception as that which you have given. I have felt in entering upon my year of office that I am a novel man. I wished to inaugurate novelties and this is one of them. I hope I may have many more in store. I have inaugurated this dinner to-night in the hope but not with the assurance that my successors will follow on with it. I see no reason, looking to the facts that almost every other profession has been recognised in this hall, why the medical profession should not be included with them. I have done it knowing what an honourable profession it is and knowing the amount of good work which it does. At this late hour of the evening I will not take up any more of your time; but I welcome you most heartily on behalf of the citizens of London and thank you most sincerely for your most kind reception.

THE GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

THE twenty-seventh Congress of the German Surgical Association was opened as usual in Langenbeck House, Berlin, on the Wednesday after Easter. That day happened this year to fall on April 13th and the meetings were continued till April 16th. The chair was taken by Professor Trendelenburg of Leipsic, who in his inaugural address informed the meeting that the family of the late Professor von Langenbeck, the founder and honorary president of the association, had bestowed on the association an endowment of 50,000 marks (£2500) in order to enable German surgeons, civil and military, to study military surgery in countries which might be the theatre of wars in which Germany was not engaged. In time of general peace prizes payable out of the annual proceeds of the endowment would be awarded to the authors of the best theoretical works on military surgery. The first subject considered by the congress was

The Improvement of the Aseptic Method in Surgery.

Professor MIKULICZ (Breslau) said that in order to avoid infection of operation wounds by the hands of the surgeons and the assistants he recommended the wearing of gloves of white thread which must be sterilised before use. To protect the wounds from germs coming from the mouth he and his assistants cover their mouths with gauze bandages. He stated that this precaution was necessary owing to the fact that in 33 per cent. of 48 cases bacteriological examination showed that staphylococcus aureus was present in the mouths of healthy persons. Speaking during the course of an operation ought to be avoided as much as possible. To ensure the sterilisation of dressing materials he has devised some methods which are apparently very useful. The most simple and efficacious way of control is to put inside the dressing-box a piece of paper on which the word "sterilised" is printed, and the paper before being sterilised is made blue by a solution of iodine, so that the printing disappears. When a temperature sufficient for complete sterilisation is produced within the apparatus the iodine goes off and the word "sterilised" reappears on the paper.

Professor LANDERER (Stuttgart) recommended that bandages treated with a 1 per cent. solution of formalin should be applied to the skin from twelve to twenty-four hours before an operation.

Dr. DÖDERLEIN (Tübingen) said that he had found that gloves such as those worn by Professor Mikulicz became filled with bacteria during operations. Gloves of caoutchouc were less infected. He did not think that gloves were of any use and he advised that surgeons should wash their hands frequently during their operations.

Dr. FRIEDRICH (Leipsic) stated that the views of the late Dr. Schimmelbusch, although correct from a theoretical point of view, were not applicable in practice. Dr. Schimmelbusch found that the bacteria present in a traumatic lesion very quickly penetrated into the blood-stream, so that the local application of an antiseptic was according to him quite useless, but it must be remembered that he made his experiments with cultures of anthrax and not with the comparatively few and innocuous germs ordinarily present in wounds. Dr. Friedrich inserted small portions of earth in the muscles of rabbits and found that the bacilli of malignant œdema did not penetrate from the wound into the circulation in less than six hours, from which it is evident that infection may be avoided if an antiseptic is applied within six hours after an injury.

Local Anæsthesia.

Dr. HACKENBRUCH (Wiesbaden) recommended injections of cocaine and eucaine especially for operations on the fingers and toes.

Dr. BRAUN (Leipsic) said that the physical properties of the injected compound were very important for efficacious anæsthesia. Only fluids which have the same freezing point as the lymphatic fluid in the tissues produce anæsthesia without either irritation or paralysis; a solution consisting of cocaine and eucaine dissolved in 0·8 per cent. salt solution would be the best. To add morphia as recommended by Dr. Schleich would not be an improvement because of the production of œdema. Local anæsthesia might even be used in major operations when general anæsthesia was either too dangerous or not possible owing to the general state of the patient. In children it is, of course, not to be used. In operations on the fingers and toes circular anæsthesia as recommended by Dr. Oberst is preferable to Schleich's method.

Dr. GOTTSTEIN (Breslau) said that in the surgical clinic of that town 233 major operations had been performed under Schleich's local anæsthesia and he mentioned the interesting fact that affections of the lungs developed as frequently after local anæsthesia as after general anæsthesia produced by chloroform and ether. According to him this frequency of pulmonary affections is due, not to the anæsthetic compound, but to the pain which hinders the patient from expectorating.

Operations on the Stomach.

Professor KRÖNLEIN (Zürich) said that his assistant, Dr. Schlatter, had last year performed a total extirpation of the stomach for carcinoma and had united the œsophagus directly with the duodenum.[1] This operation, which had been very severely criticised by American surgeons, proved a complete success. The patient is now, five months after the operation, in a good state of health, has increased in weight, and is able to eat and drink like other people. Of 21 cases operated on according to Billroth's method 5 died within a fortnight after the operation. Of the 16 remaining patients 2 died from other diseases, 8 relapsed in from one to three years after the operation, and 6 are still alive, of whom 4 were operated on four years ago.

Dr. SCHUCHARDT (Stettin) said that three varieties of carcinoma of the stomach must be distinguished, the infiltrating, the nodular, and the cauliflower-like forms. The latter is moveable and is comparatively late in extending to surrounding structures. The first two varieties are very difficult to remove completely and as a rule the greater portion of the stomach has to be excised in these cases. The last variety is more easy to operate upon and gives the best results. Dr. Schuchardt showed a stomach the whole of which, with the exception of only a small portion, was removed three years ago for carcinoma. Death ultimately occurred from pleurisy and it was then found that the piece which was left had become dilated almost to the size of a normal stomach.

Dr. STENDEL (Heidelberg) gave an account of a series of 290 operations on the stomach performed by Professor Czerny during the last eight years. The average death-rate was 24·8 per cent.; in the first year it was 45 per cent., but decreased to 16 per cent. in the last year. Pylorectomy was but seldom performed, as pyloroplasty had proved to be preferable. Of 8 cases of pylorectomy 2 are still alive after seven and eight years respectively. Of 9 cases of pyloroplasty 4 were successful, but in one case gastro-enterostomy had to be performed subsequently. The operation of gastro-enterostomy has been very much improved by the employment of Murphy's button and the mortality has decreased by 12 per cent.; it was found that the button came away in the fæces and no ill effects followed its use. Dr. Stendel finally mentioned the fact that some cases of carcinoma were cured by mere laparotomy, in the same way as has been observed in tuberculous peritonitis.

Professor MIKULICZ (Breslau) strongly urged the removal of the surrounding structures, especially the lymphatic glands, in the neighbourhood of the stomach.

Dr. DOYEN (Paris) showed his new method of pyloric operation consisting in isolation and resection of the pylorus by the aid of a *pince* invented by him, ligature of the duodenum and the stomach, and gastro-enterostomy.

Calot's Treatment of Spondylitis.

Dr. HOFFA (Würzburg) stated that 6 deaths have been reported as a sequel of Calot's treatment of spondylitis. It is especially dangerous when the spinal curvature is of several years' standing, when many vertebræ are involved, and when suppuration is going on. In other cases the method may be tried cautiously. Paresis of the lower extremities is generally improved by it. Dr. Hoffa referred to 23 cases treated by Calot's method without fatal results, but in two instances abscesses developed. The operation is generally followed by an immediate improvement in the symptoms, but it is not yet possible to give a definite opinion as to the permanency of the result.

Professor LORENZ (Vienna) said that Dr. Calot undoubtedly had the merit of having proved that an angular

[1] A translation of Dr. Schlatter's paper recording this case was published in THE LANCET of Jan. 15th 1898.

curvature of the spine will bear rough handling, but his method of treatment is unfortunately wanting in precision. Professor Lorenz has devised an apparatus by which the amount of extension is brought more directly under control; he advises that the curvature should not be straightened abruptly and by force and he is strongly of opinion that the treatment should be applied only to cases in which the vertebral column is capable of relaxation. His views have been already reported in THE LANCET of Nov. 20th, 1897 (p. 1360).

Dr. WULLSTEIN (Halle) said that he had made observations on dead bodies in which the vertebral column had been broken in accordance with Calot's directions and he had found laceration of the pleura and the lungs, hæmorrhage of the dura mater, laceration of the spinal cord, &c. The curvature ought to be straightened gradually, as the application of great force is liable to produce the lesions just enumerated. New formation of bone in the space between the vertebral fragments was not possible, as has been alleged by Dr. Calot.

The majority of other speakers, such as Dr. SCHEDE, Dr. KÖNIG, Dr. KÜMMELL, &c., were of opinion that Calot's method was not universally applicable and that angular curvature of the spine could be successfully treated only in the early stage of the disease and by a less energetic procedure.

Operations for Empyema.

Dr. JORDAN (Heidelberg) said that Estlander's method of subperiosteal resection of the ribs had not given good results, for of 8 cases only 2 were successful. In protracted cases Schede's operation is preferable as all the fistulæ are made visible. The resection must be a radical one. Of Dr. Jordan's patients 9 were cured, 5 were improved, and 1 is still under treatment. In children the results are still better than in adults. The operation may be performed on tuberculous patients provided that their general state is not bad. On one occasion Dr. Jordan successfully carried out Delorme's method of removing fibrinous masses on the pulmonary pleura. Of 27 cases described in the medical press 11 were cured in this way.

Dr. PERTHES (Leipsic) recommended that a Bunsen's air-pump, which is worked by a column of falling water, should be connected with the cannula in the pleural cavity by means of a caoutchouc tube, so that the rarefaction of air produced by the pump might make the lung dilate.

Dr. KAREWSKI (Berlin) showed patients on whom he had operated for abscess of the lung as well as a patient suffering from actinomycosis who had been nearly cured by resection of the thoracic walls and cauterisation of the affected portion of the lungs by Dr. Paquelin's thermo-cautery.

The Serum Treatment of Diphtheria.

Professor KRÖNLEIN (Zürich) exhibited Statistical Tables, which showed (1) that the prevalence of diphtheria in the canton of Zürich had been nearly uniform during the past fifteen years; and (2) that the mortality rapidly decreased as soon as antitoxin serum was used on a somewhat large scale. In his clinic all the patients were examined bacteriologically and serum was administered in every case of diphtheria without exception. This was the only way of arriving at accurate statistical results. Of 1336 cases treated before the serum-period 554 (=39·4 per cent.) died, whilst during the serum-period there were 55 deaths among 437 cases (=12 per cent.). In cases of tracheotomy the death-rates before and during the serum period were 66 and 38·8 per cent. respectively; and, moreover, the operation is now performed much less frequently than before. The good effects of antitoxin serum were shown by rapid improvement of the patient's general state, decrease of temperature, loosening of the croupous membranes, decrease of glandular swelling, absence of tracheal croup and stenosis, and absence of diphtheritic infection of the tracheotomy wound.

Rifle Bullets of the British Army.

Professor VON BRUNS (Tübingen) made a communication relative to the bullets used by the British army in recent warfare. These projectiles were originally coated with nickel, but as it was found that the enemy when wounded were not invariably disabled the nickel coating was filed away from the top of the bullet. In fact, the nickel covering enabled the bullet to pass through the body making only a relatively small wound, but when this covering was removed from the top the lead was flattened out as soon as it struck the body, by which flattening the remainder of the covering was burst open in an explosion-like way, inflicting wounds of an astonishingly severe character. These bullets, which are termed Dum-Dum bullets, are now officially introduced into the British army. In experiments made with them on dead bodies Professor von Bruns found that shots fired at distances of from 25 to 50 metres (from 80 to 160 yards) caused wounds of the skin as large as a hand, the muscles were lacerated, great pieces of bone were torn out, and the wound was filled with fragments of lead and nickel. Professor von Bruns said that these bullets were in accordance with the letter but not with the spirit of the Convention of St. Petersburg, by which the use of explosive projectiles was prohibited. The convention would therefore have to be amended and he would be glad if the discussion of the question by the Surgical Association would have the effect of inducing the German Government to take the necessary steps.

Operations on the Liver and Gall-bladder.

Dr. PETERSEN (Heidelberg) gave an account of 162 Operations on the Liver and Gall-bladder performed in the surgical clinic by Professor Czerny. In 65 cases single cholecystotomy was performed, in 1 case cystotomy by two successive operations, in 6 cases dialysis, in 3 cases cholecystopexy, in 10 cases cholecystectomy (with 2 deaths), and in 20 cases choledochotomy (with 4 deaths). Choledochoduodenostomy was performed on 11 patients, with 4 of whom Murphy's button was used. Single cystotomy must be the normal operation. Cystectomy must be resorted to in cases of malignant growths. In 2 of the cases of cholecystotomy some calculi were left behind; the other patients did not relapse. Biliary fistulæ were established in 8 instances, but it was found that they did not occur when drainage-tubes were inserted in the gall-bladder after the operation. In 50 cases the bile was examined bacteriologically, with the result that colon bacilli were found in 38 cases, streptococci in 6, and staphylococci in 4. After the operation the bacteria usually decreased rapidly. Carcinoma was present in 30 cases and sarcoma in 3 cases.

Dr. RIEDEL (Jena) said that death after operation may be caused by infection of the bile. In the great majority of cases the bile is aseptic, so that it may penetrate into the peritoneal cavity without any harm, but on the other hand it may contain pathogenic bacteria. It is difficult to say before the operation whether the bile is infected or not, but patients with healthy bile generally feel well when the fit is over, whilst those whose bile is infected become cachectic. Patients of this kind are lost with or without operation.

Dr. FRANKE (Brunswick) showed some Gall-stones which had been broken by a medical man who had applied manual force through the abdominal walls without laparotomy. The fragments lacerated the gall-bladder and an abscess of the liver developed.

Space permits only a passing reference to the other papers read at the meetings of the association, the principal of them being as follows: by Dr. VON ZOEGE MANTEUFFEL (Dorpat) on Volvulus; by Professor VON BRAMAN (Halle) on Intestinal Resection for Carcinoma; by Dr. DOYEN (Paris) on Operations on the Brain; by Professor GARRÉ (Rostock) on Resection of the Œsophagus, &c.

At the final meeting Professor Hahn of Berlin was elected president. Of British members Mr. Arthur E. Barker of London and Professor Alexander Ogston of Aberdeen were present.

LITERARY INTELLIGENCE. — Messrs. Baillière, Tindall, and Cox inform us that they have the English agency for Kobert's "Practical Toxicology" which was noticed in our columns last week. They will publish during the next few days a "Manual of Surgery" by Professor Wm. Rose of King's College Hospital, and Mr. Albert Carless, Teacher of Operative Surgery in King's College. The work will take a place between the large text-books and the smaller manuals which are not now deemed sufficient for examinational purposes. They will also publish "Outlines of Practical Surgery" by Mr. W. G. Spencer of the Westminster Hospital and a new edition of Pearmain and Moor's "Manual of Applied Bacteriology," with coloured plates, the first edition of which has run out in a few months.—Messrs. Munns and Allen, Broad-street, Birmingham, have published a booklet of 48 pages containing a useful collection of annotations on the British Pharmacopœia of 1898, with remarks on the important differences between the present Pharmacopœia and its predecessor of 1895 and the additions of 1890. The price is 1*s*. The author is Mr. Thomas Chase, pharmaceutical chemist, Five Ways, Edgbaston, Birmingham.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—**At the Convocation held on April 23rd the following degrees were conferred:—**

Doctor in Medicine.—Ernest Chittenden Bridges, M.B., B.S. Durh.; Robert Cunyngham Brown, M.B., B.S. Durh.; Harry Crichton, M.B., B.S. Durh.; Charles Holmes Joy, M.B., B.S. Durh.; Nicholas Magoris, M.B., B.S. Durh.; William Rawes, M.B. Durh.; William Rushton Shortt, M.B., B.S. Durh.; James Ward Summerhayes, M.B. Durh.; and William Edwyn Falkingbridge Tinley, M.B., B.S. Durh.

Doctor in Medicine (Practitioners of Fifteen Years' Standing.)—Moses George Biggs, M.R.C.S., L.S.A.; Francis Charles Bryan, M.R.C.S., L.S.A.; William Lindsay Chubb, M.R.C.S., L.R.C.P.; William Darley-Hartley, M.R.C.S., L.R.C.P.; Charles Graham Havell, M.R.C.S., L.R.C.P.; Henry Martin Lightoller, M.R.C.S., L.R.C.P., L.S.A.; Justin McCallum McCarthy, M.R.C.S., L.S.A.; Lawrence Willmer Kinglake Phillips, M.R.C.S., L.S.A.; and Alfred James Turner, L.S.A.

Master in Surgery.—John William Henry Eyre, M.D., B.S. Durh., and Ernest Robert Kendall, M.B., B.S. Durh.

Bachelor in Medicine.—Thomas George Drabble Adams, College of Medicine, Newcastle-upon-Tyne; Henry Edward Montgomery Baylis, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; John Thomson Bell, College of Medicine, Newcastle-upon-Tyne; Francis Ward Crossman, M.R.C.S., L.R.C.P., and Herbert James Godwin, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; John Harris, B.A., Guy's Hospital; Frederick Charles James, M.R.C.S., L.R.C.P., and Howard Percy Kennard, St. Thomas's Hospital; Ralph Albert Rogers Lankester, University College Hospital; Harold Turner Newton and Theodore John Phillips, College of Medicine, Newcastle-upon-Tyne; Arthur Montague Rygate, M.R.C.S., L.R.C.P., Guy's Hospital; Reginald Charles Jeremie Stevens, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Thomas John Augustus Tulk-Hart, M.R.C.S., L.R.C.P., Guy's Hospital; and Percy Edward Turner, M.R.C.S., L.R.C.P., and Maurice Dale Wood, St. Bartholomew's Hospital.

Bachelor in Surgery.—Thomas George Drabble Adams, College of Medicine, Newcastle-upon-Tyne; Henry Edward Montgomery Baylis, M.R.C.S., L.R.C.P., St. Batholomew's Hospital; John Thomson Bell, College of Medicine, Newcastle-upon-Tyne; Francis Ward Crossman, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; John Harris, B.A., Guy's Hospital; Howard Percy Kennard, St. Thomas's Hospital; Ralph Albert Rogers Lankester, University College Hospital; Harold Turner Newton and Theodore John Phillips, College of Medicine, Newcastle-upon-Tyne; Reginald Charles Jeremie Stevens, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; John Augustus Tulk-Hart, M.R.C.S., L.R.C.P., Guy's Hospital; and Percy Edward Turner, M.R.C.S., L.R.C.P., and Maurice Dale Wood, St. Bartholomew's Hospital.

At the third examination for the degree of Bachelor in Medicine held at the College of Medicine, Newcastle-upon-Tyne, in April, the following candidates satisfied the examiners:—

Second-class Honours.—Howard Henry Congreve Dent, M.R.C.S., L.R.C.P., Mason College, Birmingham, and Norman Christian Balles, College of Medicine, Newcastle-upon-Tyne.

Pass List.—Solomon Cross, George Oswald Morrell Dickenson, and Harold Ben Fawcus, College of Medicine, Newcastle-upon-Tyne; Charles Edward Fenn, King's College, London; Charles Thomas Holmes, John Rutherford Halliday, Douglas Hethcote, and Ernest Inman, College of Medicine, Newcastle-upon-Tyne; Samuel Percy Johnson, Mason College, Birmingham; Maurice Jacobs, James Milligan, James Muirhead, and Robert Lowis Routledge, College of Medicine, Newcastle-upon-Tyne; Grace Harwood Stewart, London School of Medicine for Women; and Edward Norman Threlfall, Charles Augustus Vogwell, and David Henderson Weir, College of Medicine, Newcastle-upon-Tyne.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—**At the April sittings of the Examiners of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, held in Glasgow, the following candidates passed the respective examinations:—**

First Examination, Five Years' Course.—John William Isbister, Glasgow; David Joseph Cagney, Blarney, Cork; David Moodie, Whiteinch; Joseph R. W. Sutton, Cork; William Thomson, Glasgow; James Joseph Egan, Galway; Anthony H. Corley, Belfast; Hugh Williams, Glasgow; Frederick A. Georgeson, Edinburgh; and Syed Zamiruddin, Glasgow.

First Examination, Four Years' Course.—John Gemmel Welsh, Irvine; William Hunter, Sunderland; Patrick Park, Belfast; John Allison Maclardy, Glasgow; Richard M'Kim Wilkin, Belfast; Jas. Ebenezer Boon, Glasgow; George M. Freke, Edinburgh; and Joseph C. Shelmerdine, Partick.

Second Examination, Five Years' Course.—James Noble, Pollokshields; David Crombie, Crossmyloof; Charles Wm. Sharp, Glasgow; John Bell Walker, Rutherglen; David S. Erskine M'Nab, Shotts; Percival Horace Rainbird, Glasgow (with distinction); Harry Miller Roberts, Pollokshields; William M. Battersby, Glasgow (with distinction); John Campbell Douglas, Greenock (with distinction); Peter M'Kellar Dewar, Glasgow; John Tudor Griffiths, Glasgow; William Burns, Belfast; Alice Miles, Glasgow; William Turner, Glasgow; Joseph Burnard O'Mahony, Midleton, County Cork; Robert Elwell-Nalsh, Glasgow; and Francis Andubon Gray, Edinburgh.

Second Examination, Four Years' Course.—Arthur Clarence Turner, Londonderry; John M'Elroy, Glasgow; Bartholomew Francis Murphy, Edinburgh; Lawson S. Shennan, Edinburgh; Arthur Mellor Crosfield, Edinburgh; John Eilul, Edinburgh; Oliver Scanlan, Glasgow; and Andrew Snody Omand, Edinburgh.

Third Examination, Five Years' Course.—James Valentine Roche, Edinburgh; Thomas Richard W. Atkins, Edinburgh; Reginald Storrs, London; Joseph Fulton, Antrim; David Fyfe, Glasgow; Albert Sophron Sieger, Greenock; John Thomas Moore, Dublin; Thomas Day Bird, Glasgow; and Charles M'Donnell, Edinburgh.

Final Examination, and admitted Licentiates of the Three Colleges.—Hugh Macpherson, Oban; Edwin Thomas Walker, Smethwick; Harry Lowick Phelps, Bishopton, Bristol; Henry Gard, Devonport; Robert Mackie, Glasgow; James M'Glynn, Castlederg; Kenneth F. Lund, Liverpool; Arthur Frederick Seacome, Rock Ferry, Cheshire; John Boyd, Dublin; Hugh Owen Jones, Festiniog (with honours); John Farmer, Clydebank; Hugh Joseph Fern, Greenock; Andrew M'Credie, Stranraer; and John Francis M'Givern, Melbourne.

UNIVERSITY OF CAMBRIDGE.—**At the congregation on April 28th the following medical and surgical degrees were conferred:—**

Bachelor of Medicine and Bachelor of Surgery.—R. A. Yeld, B.A., Trinity; C. C. Stead, B.A., Caius; A. Trethewy, B.A., Caius; and E. J. Woolley, B.A., Caius.

Bachelor of Medicine.—G. F. McCleary, B.A., Trinity Hall.

"Paley's Evidences" have been retained as one of the subjects of the Previous Examination by the Senate. There were 109 votes for the subject and 70 against.

APOTHECARIES' HALL OF IRELAND.—**The following candidates at the examinations in April passed in the subjects indicated:—**

Physics and Chemistry.—G. O'Callaghan Walsh.
Biology.—R. Treacy and G. O'Callaghan Walsh.
Anatomy.—R. Treacy.
Second Professional Examination: Advanced Anatomy.—R. Tichborne.
Third Professional Examination: Pathology.—F. E. Bass.

UNIVERSITY OF LONDON.—**At the meeting of the Senate held on April 27th the following were among the gentlemen elected examiners for 1898-9:—Mental and Moral Science: Professor S. Alexander and Professor William Knight, LL.D. Mathematics and Natural Philosophy: Mr. E. W. Hobson, Sc.D., F.R.S., and Mr. Joseph Larmor, D.Sc., F.R.S. Experimental Philosophy: Professor G. F. FitzGerald, F.R.S., and Professor Silvanus Thompson, D.Sc., F.R.S. Chemistry: Professor Wyndham R. Dunstan, F.R.S., and Professor William Ramsay, Ph.D., LL.D., F.R.S. Botany and Vegetable Physiology; Professor F. W. Oliver, D.Sc., and Professor J. W. H. Trail, M.D., F.R.S. Comparative Anatomy and Zoology: Mr. F. E. Beddard, F.R.S., and Professor G. B. Howes, LL.D., F.R.S. Geology and Physical Geography: Professor T. G. Bonney, Sc.D., LL.D., F.R.S., and Professor Charles Lapworth, LL.D., F.R.S. Practice of Medicine: Dr. W. H. Allchin and Dr. Frederick Taylor. Surgery: Mr. William Anderson and Mr. W. Watson Cheyne, F.R.C.S. Eng., F.R.S. Anatomy: Professor G. D. Thane and Professor A. H. Young, M.B. Physiology: Professor J. G. McKendrick, M.D. Aberd., F.R.S., and Professor E. A. Schäfer, LL.D., F.R.S. Obstetric Medicine: Dr. G. E. Herman and Dr. Peter Horrocks. Materia Medica and Pharmaceutical Chemistry: Dr. D. J. Leech and Dr. Sidney Phillips. Forensic Medicine: Professor J. Dixon Mann, M.D. St. And., and Dr. Thomas Stevenson. State Medicine: Dr. Arthur Newsholme and Dr. Edward Seaton. Mental Physiology: Professor S. Alexander and Dr. T. Claye Shaw.**

ROYAL INSTITUTION.—On Friday evening, April 29th, Professor Andrew Gray delivered a discourse on Magneto-optic Rotation and its explation by a gyrostatic medium. In the principal optical experiment which was shown a rod of Faraday's "heavy glass" (borate of lead) mounted between two Nicol's prisms was traversed by a beam of light. When the prisms were crossed the transmitted light gave only a very faint disc on the screen, but when a magnetic field was created by passing a galvanic current through a coil of wire surrounding the glass rod the illumination of the disc was distinctly increased without any change in the position of the prisms. Lord Kelvin has suggested that the phenomena point to molecular motion in the medium being the cause of this magnetic rotation of the plane of polarisation, while the so-called "natural" rotation produced by solutions of sugar and many other substances is probably due to the structure of the medium. Precessional motion and other effects produced by gyrostats were shown, as well as a gyrostatic pendulum, which constantly changed its plane of vibration, tracing looped figures which were shown on a horizontal blackboard by means of a stream of white sand falling from the pendulum.

FRENCH HOSPITAL AND DISPENSARY. — The thirtieth annual dinner for the benefit of this institution takes place this (Saturday) evening at the Hotel Cecil, His Excellency the French Ambassador in the chair, supported by the Lord Mayor and Sheriffs of London.

LLANELLY HOSPITAL. — Owing to some unpleasantness among the nursing staff of Llanelly Hospital the committee recently decided to accept the resignations of the matron and nurses, who accordingly left on April 28th, and another matron has been placed temporarily in charge. The committee had (as was stated in THE LANCET of April 30th) intended to close the institution for the purpose of replacing the staff but now find that there will be no necessity to do so.

THE SAVAGE CLUB AND THE MEDICAL PROFESSION.—On Saturday, May 7th, at the House Dinner of the Savage Club the Medical Profession will be strongly represented. Among the guests of the Chairman (Mr. J. Y. W. MacAlister) will be the Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England (Sir Samuel Wilks and Sir William MacCormac), Sir Dyce Duckworth, Sir William Gowers, Sir Thomas Smith, Professor David Ferrier, Dr. Church, Dr. C. J. Hare, Mr. Thomas Bryant, Mr. Warrington Haward, and others.

THE RECOVERY OF MEDICAL FEES.—At Totnes County Court, on April 25th, Judge Woodfall read a judgment of Judge Edge *re* Dr. K. R. Smith *v.* Mrs. Payne Collier. Plaintiff, a medical man of Totnes, sued defendant for £41 for medical attendance and medicine. Judge Edge stated that there was no doubt that plaintiff was employed by defendant, that she was in possession of a free and separate estate which would reasonably bind her to any contract, and that the evidence showed that the maintenance of Mr. and Mrs. Payne Collier and their family depended upon Mrs. Payne Collier's income, which was about £500 or £600 per annum. Judgment was given for plaintiff with costs.

DIPHTHERIA IN LONDON.—The decrease in the amount of diphtheria in London chronicled in the four weeks ended on March 26th as compared with the like period ended on Feb. 26th has been fully maintained in the four weeks concluded on April 23rd. In the March period the total of notified cases was 813 and the successive weekly numbers were 202, 174, 221, and 216. But in the April period the weekly figures only once reached 200, having been 182, 174, 203, and 170, the tendency to increase in the third week of the period having been spasmodic only. The aggregate of these four totals, 729, falls short by 84 of that for the March period and the weekly average of the earlier month of 203 gives place to one of 182 notified cases. In March one district escaped invasion, in April all districts reported cases, although in 6 of them only 12 cases in all were recorded. In each period two districts had upwards of 50 cases each, the same two districts, moreover, being in question, the total of 140 in these areas in March being replaced by 131 in April. In the matter of fatal diphtheria the weeks of the earlier month recorded 38, 33, 36, and 53 deaths respectively, an average of 40 per week, and a total of 160. In April the successive figures were 45, 29, 34, and 31, an average of 35 deaths per week, and a total of 139. Here, then, also we see a fall; and the case mortality, which had been 19·7 per cent. in March, declined to 19·1 per cent. in April. In the Outer Ring the registered deaths have, on the whole, remained much the same in the two periods—namely, 22, 19, 10, and 16, or 67 in all in March, and 15, 13, 21, and 16, or 65 in all during the April period.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Irish Local Government Bill.

THIS measure is slowly making its way through committee of the whole House. Clause 9, dealing with the future provision and management of lunatic asylums, occupied a very long time in its discussion, but though a great many amendments were moved few were carried and the clause practically remains in its original form. A proposal was made by Mr. Lecky that instead of entrusting lunacy administration to county councils the Government should keep it in its own hands and meet the cost out of the Imperial funds. The proposal, however, was resisted by the Government and defeated by a large majority.

Midwives Registration Bill.

The second reading of this measure stands as the first order for Wednesday of next week, but it is open to the Government to put the Irish Local Government Bill in front of it, and this course is almost certain to be adopted. If it is, then the Midwives Bill will be relegated to the crowd of private members' Bills which have practically no chance of being discussed during the present session.

HOUSE OF COMMONS.

THURSDAY, APRIL 28TH.

Lead Poisoning in the Potteries.

Mr. M'Kenna asked the Home Secretary whether he had received a petition from working potters in Burslem, Hanley, and the district in which the recent deaths, blindness, and other suffering from lead poisoning had occurred asking that a female inspector be appointed for the potteries; and whether, in view of the large number of women and young persons employed, amongst whom the greatest sufferers from lead poisoning are found, he would consider the desirability of appointing a female inspector to take charge of the district under the control of the chief inspector.—Sir Matthew White Ridley replied that he had received the petition to which the hon. Member referred and he had consented to receive a deputation from the district on the subject. In these circumstances he should prefer not to make any statement at present.

Medical Referees in Scotland.

Sir John Leng asked the Home Secretary whether he would appoint medical referees in Scotland as well as in England under the Workmen's Compensation Act of last session, and, if so, whether any special regulations would be made with regard to their qualifications and duties.—Sir Matthew White Ridley replied that he proposed to appoint medical referees in Scotland and the regulations would be the same as in England with such variation in details as might be made necessary by the differences between county courts in England and sheriff courts in Scotland. On this latter point he was in communication with the Scottish Office.

Venereal Disease in the Straits Settlements.

Mr. Chamberlain, replying to questions on this subject, said: I informed the Straits Settlements Association, in reply to their letter of Nov. 8th, that I was not prepared to sanction the re-enactment of the Contagious Diseases Ordinances in the Straits Settlements, but that I was conferring with the Governor as to whether other measures could be taken to check the spread of venereal diseases in that colony. The correspondence with the Governor is not yet completed, but when it is it will be laid before the House.

FRIDAY, APRIL 29TH.

Experiments on Living Animals.

Mr. Jesse Collings moved for a return showing the number of experiments performed on living animals during the year 1897 under licences granted under the Act 39 & 30 Vict. c. 77, distinguishing painless from painful experiments (in continuation of Parliamentary Paper No. 239 of Session 1897).—Mr. Swift MacNeill said he did not wish to oppose the return but he complained that the information given was incomplete and misleading. The return ought to show not the number of experiments but the number of animals experimented upon, because one experiment in a line of scientific research might involve the lives of as many as 40 or 50 animals. Last year there were 7500 experiments and that would give the public to understand that only that number of animals were killed. Again, a distinction was carefully drawn between painful and painless experiments, but that was most misleading because "painless" only meant that the experiment was made under the influence of an anæsthetic and took no account of the subsequent suffering of the animal. He would also like to have information in the return as to the number of visits paid by the inspectors.—Mr. Collings, in reply, said that the return was perfectly fair and honest so far as it went, but if the hon. Member would communicate with the Home Office and explain his views as to the form the return should take he would see what could be done in another year. The motion was then agreed to.

The Troops and Civil Practitioners.

Captain Norton asked the Under Secretary of State for War whether, before employing civil practitioners in affording medical aid to the troops, every effort had in the past been made to obtain for that purpose the services of retired army medical officers, whether these be retired on pension and liable to recall or retired on a gratuity, and whose names appeared in the monthly army list up to December, 1897, as liable to recall.—Mr. Brodrick replied that every effort was being made to utilise the services of suitable retired medical officers, whether retired upon gratuity or otherwise. The preference, however, was given to those who were in receipt of retired pay.

Rabies in Surrey.

Mr. Skewes-Cox asked the President of the Board of Agriculture whether he was now in a position to withdraw the Dog Muzzling Order so far as it affected the administrative county of Surrey.—Mr. Walter Long replied: I am afraid that the time has not yet come for the withdrawal of the muzzling order now in force in Surrey. Four cases of rabies have occurred there during the past six months and in view of the proximity of the county to the metropolis and of the fact that the disease had been more or less prevalent within its area for several years past the relaxation of the Order at the present time would probably endanger the success of our operations and render the re-imposition of the muzzle necessary at no distant date.

The Tuberculosis Report.

Mr. Channing asked the President of the Board of Agriculture whether effect would be given to the recommendation made last August by one of Her Majesty's Commissioners on Agricultural Depression, and now made again in the recently issued report of the Royal Commission on Tuberculosis, that facilities should be provided at the expense of the State for the voluntary application of the tuberculin test to cattle, with a view to the gradual elimination of tuberculosis by the Danish method, and whether a supplementary estimate be presented for this purpose.—Mr. Walter Long replied: As

the hon. Member is aware the report of the Royal Commission to which he refers was only circulated on Tuesday last and the minutes of evidence and other documents are not as yet available. In any case, however, it is, I think, clear that it would be premature for me to submit to the Chancellor of the Exchequer any proposals for expenditure in the direction suggested until representative agricultural bodies have had an opportunity of considering the recommendations made by the committee and I am in a position to form some idea as to the extent to which stock-owners would be likely to avail themselves of the facilities proposed to be given.—Mr. Channing gave notice that he would seek an opportunity of calling further attention to the subject.

MONDAY, MAY 2ND.

Roentgen Rays in the Soudan.

Sir Alfred Hickman asked the Under Secretary of State for War whether he was aware that the medical staff with the army in the Soudan were not provided with the Roentgen rays apparatus; and whether he would take steps to supply the deficiency.—Mr. Brodrick replied that the Roentgen rays apparatus for field service required special construction. One was made for Egypt and was despatched thither on April 5th, together with a large one for use in the Station Hospital at Cairo.

Medical Examination for the Civil Service.

Colonel Dalbiac asked the Secretary to the Treasury, as representing the Postmaster-General, if the rule had been abolished enabling the refunding of medical fees paid by candidates who, having failed to pass the departmental doctor's examination, had been granted a re-examination by a medical board and had successfully passed it; by whom should the fee paid for the second medical examination be refunded; and was he aware that in a recent case in the South-Eastern District Office the Controller denied the liability of the department and referred the applicant to the Civil Service Commissioners, who, however, on March 1st replied that they were not liable for any of the expenses incurred in connexion with the special medical examination.—Mr. Hanbury replied that so far as the Postmaster-General was aware there never had been a rule for the repayment of medical fees to candidates for appointment in the Post Office who having failed to pass the departmental medical officer's examination, had been granted a re-examination by a medical board and had successfully passed it. For the examination by the medical officer of the Post Office no fee was charged to the candidate, but with the re-examination the Post Office had nothing to do. This when granted was granted by the Civil Service Commissioners and was not confined to Post Office candidates, and the Postmaster-General had ascertained that one of the conditions on which it was granted was that all expenses must be borne by the candidate whatever might be the result. In the particular case to which the hon. Member referred the circumstances appear to have been properly explained to the candidate.

TUESDAY, MAY 3RD.

The Sanitation of Post Offices.

Mr. Hanbury, replying to a question on this subject, said that all post-offices which were not provided by the Department itself were subject to inspection by the local sanitary authorities. Crown post-offices—that was to say, those provided by the Department—were, like other buildings the property of the Government, exempt from inspection by the local sanitary authority. The Postmaster-General was responsible for the supervision of the sanitary condition of these offices and by his direction the sanitary arrangements were under constant supervision by the officers in charge as well as by the local medical officers to the Department. They were also supervised by the professional officers of the Board of Works. When a sanitary inspector desired to visit one of these offices the officer in charge was instructed to obtain authority for him to do so. Whenever the staff of any office complained of inadequate arrangements for safeguarding their health the complaint was immediately investigated and steps were taken to apply any remedies that might be found necessary and practicable. In the circumstances it was not at present considered necessary that the local sanitary inspector or factory inspector should have further facilities for investigation.

The Plague in India.

Lord George Hamilton, in answer to Sir Mancherjee Bhownaggree, said that the despatch from the Government of Bombay on the riots which took place in that city in the beginning of March had been received. The Bombay Government were of opinion that the riots were not the result of political agitation or deliberately planned, but were merely a sudden ebullition of disorder among an uneducated and fanatical section of the community. They added that the leading representatives of all classes had exerted themselves to allay excitement. The despatch and enclosures would be included in the next set of plague papers laid upon the table.—Lord George Hamilton, replying to a question addressed to him by Sir John Leng, said that his latest information regarding the plague at Calcutta was dated May 1st and 2nd. The existence of local plague cases, he regretted to say, had been placed beyond doubt and instructions had been given for carrying out the preventive precautions prescribed by the Venice Convention. 23 cases of plague and 7 deaths occurred during the last four days of April. He was confident that the Government in combating the plague at Calcutta would give due weight to the religious sentiments of the people and would make every endeavour to obtain their coöperation.

Phossy Jaw in the Match Trade.

Sir Charles Dilke asked the Home Secretary whether his attention had been called to an inquest held at Bow on Saturday concerning the death from "phossy jaw" of a match dipper, aged twenty-two years, employed at Bryant and May's, and to the coroner's remarks upon the conduct of the manager of the factory; and whether he would consider if the time had come to prohibit the manufacture and importation of the class of matches requiring the employment of the more dangerous kind of phosphorus.—Mr. Pickersgill also asked the right hon. gentleman whether his attention had been called to the report of an inquest held at Bow on Saturday last on the body of Cornelius Lean, lately employed at the match factory of Messrs. Bryant and May, from which it appeared that Lean was poisoned by the yellow phosphorus used in the manufacture; that the factory doctor, who admitted that the death was due to "phossy-jaw," gave no indication of this fact on the certificate of death; and that the coroner commented on the apparent desire to hush the whole matter up, whether the factory doctor gave the notice to the chief inspector of factories required by sub-section (1) of section 29 of the Factory Act, 1895; whether the occupier of the factory gave the notices to the inspector and to the certifying surgeon for the district required by sub-section (3) of the same section; whether an inspector or some person on behalf of the Secretary of State was present at the inquest to watch the proceedings in accordance with section 19 of the same Act; if not, did the coroner send to the inspector the notice of the holding of the inquest required by that section, and, if such notice was sent, why did not the inspector attend; and what steps did he now propose to take in the matter.—Sir M. White Ridley replied: My attention has been called to this inquest. The case was not notified either by the occupier or the factory medical officer and the explanation given by the latter that he was not sure of the diagnosis appears to me to be far from satisfactory. In addition to the provisions of section 29 of the Act of 1895 the special rules in force in the factory required every case where there was any symptom of necrosis to be reported. The factory inspector attended the inquest and has visited the works. He reports that in other respects the special rules have been observed. I propose, however, to make further inquiries into the case. No other cases of phosphorus poisoning have been reported since the Act of 1895 and I do not therefore think that I should be justified in the unconditional prohibition of the use of yellow phosphorus.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ANDERSON, GEORGE, M.B., C.M. Edin., has been appointed a Medical Officer for the Swinefleet Sanitary District of the Goole Union.

BAILEY, JOHN GEORGE, M.B., C.M. Edin., has been appointed Resident Medical Officer for the Victoria Hospital, Burnley, vice J. S. Warrack, resigned.

BLACKLOCK, J., M.D. St. And., has been appointed a Medical Officer for the Brindle Sanitary District of the Chorley Union.

BLAXALL, F. R., M.D. Lond., D.P.H. Camb., has been appointed a Bacteriologist by the Local Government Board.

BURGESS, A., M.D., B.Ch. Irel., has been appointed a Medical Officer for the Home No. 1 Sanitary District of the Lincoln Union.

CLUCKIE, N. G., M.B. Glasg., L.F.P.S., has been re-appointed Ophthalmic Surgeon for the Victoria Eye Infirmary, Paisley.

COOKE, WILLIAM H., M.D. Brux., M.R.C.S., L.R.C.P., L.S.A., has been appointed an Honorary Medical Officer to the Eastern Dispensary and Anæsthetist to the Royal United Hospital, Bath.

DONALD, ARCHIBALD, M.B., C.M. Glasg., D.P.H., has been appointed an Assistant Surgeon for the Victoria Eye Infirmary, Paisley.

DYSON, M. G., L.R.C.P. Lond., M.R.C.S., has been appointed First Resident Assistant Medical Officer for the St. John's-road Workhouse and Infirmary of the Parish of St. Mary, Islington.

FOX, EDWARD LAWRENCE, M.A., M.D., B.Ch. Cantab., M.R.C.P. Lond., M.R.C.S. Eng., has been appointed an Honorary Physician to the Plymouth Royal Eye Infirmary.

GAINS, J. E., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Garforth Hospital.

GARDNER, WM., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Nunney Sanitary District of the Frome Union.

GIDDY, C. F., M.B., C.M. Edin., has been appointed a Government Surgeon for the Colonial Hospital, Singapore.

GORDON, J. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Medical Officer for the Dalwood and Stockland Sanitary District of the Axminster Union.

HARNESS, H. NELSON, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon for the Royal Cornwall Infirmary, Truro, Cornwall.

HAYES, T. C., M.A., M.D., has been elected Professor of Obstetric Medicine and Diseases of Women and Children by the Council of King's College, London.

HOWARD, J. A., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed a Medical Officer for the Seventh Sanitary District of the St. Saviour's Union.

HOWES, F. C. P., M.D. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Home No. 2 Sanitary District of the Lincoln Union.

KENDALL, N. F., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Chiddingfold Sanitary District of the Hambledon Union.

LEVICK, H. DRIFFIELD, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Senior Resident Medical Officer to the Royal Free Hospital, Gray's-inn-road, London.

LIGHTBURNE, E. A., L.R.C.S., L.R.C.P., has been appointed Police Surgeon for Bow, London.

MACGILL, H. M., M.B., C.M. Edin., has been appointed a Medical Officer for the Hartlepool Sanitary District of the Hartlepool Union.

MACLAREN, J. A., M.B., Ch.B. Vict., has been appointed a Second Resident Assistant Medical Officer for the Workhouse of the Township of Manchester.

MELLISH, J. S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Wells Port Sanitary Authority.

MORRIS, S. GLANVILLE, M.D., M.S., has been appointed Certifying Factory Surgeon for the District of Nantgaredig, Carmarthen.

MUDGE, JAMES, M.R.C.S., L.R.C.P. Edin., L.S.A., has been re-appointed Medical Officer of Health by the West Penwith (Cornwall) Rural District Council.

O'RAFFERTY, J. C., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Medical Officer for the First Sanitary District of the Daventry Union.

PADBURY, G. J., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed a Medical Officer for the Kilmington Sanitary District of the Axminster Union.

PARRY, GEORGE HEARN, M.B., C.M. Edin., has been appointed Assistant Resident Medical Officer for the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor, Isle of Wight.

PARSONS, ALLAN C., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Physician to the Royal Free Hospital, Gray's-inn-road, London.

PATON, G. A., L.R.C.S. Irel., has been appointed a Medical Officer for the Second and Third Sanitary Districts of the St. Saviour's Union.

PHILLIPS, JOHN, M.A., M.D., has been elected Lecturer in Practical Obstetrics by the Council of King's College, London.

PRESTON, C. H., F.R.C.S., L.D.S., has been appointed an Honorary Dental Surgeon for the Manchester Children's Hospital, Pendlebury and Garside street.

PRITCHARD, W. B., L.R.C.P. Lond., M.R.C.S., has been appointed an Assistant Medical Officer for Home Patients, Manchester Infirmary.

PROBYN-WILLIAMS, R. J., M.D. Durb., L.R.C.P., M.R.C.S., has been appointed Assistant Anæsthetist for the Dental Hospital of London.

SMITH, GUY BELLINGHAM, M.B., B.S., F.R.C.S. Lond., has been appointed a Surgeon to the Surrey Dispensary.

TAYLOR, FRANK E., M.A., M.B., Ch.B., B.Sc. Vict., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Hospital for Women and Children, Leeds.

TAYLOR, F. R. P., M.D. Lond., B.S., L.R.C.P., M.R.C.S., has been appointed, *pro tem.*, Medical Superintendent for the Darenth Adult Asylum.

THURSFIELD, W., M.D. Aberd., L.R.C.P. Lond., M.R.C.S., has been appointed a Consulting Physician for the Bridgnorth and South Shropshire Infirmary, vice B. Fletcher.

WILLIAMS, RALPH PAUL, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Royal Free Hospital, Gray's-inn-road, London.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BURTON-ON-TRENT INFIRMARY.—House Surgeon. Salary £130 per annum, with prospect of increase, and rooms in the infirmary free, also coals and gas.

CITY AND COUNTY OF BRISTOL.—Medical Officer for the Workhouse. Salary £250 per annum, with an allowance of £30 per annum for rent. Applications to the Clerk to the Guardians, St. Peter's Hospital, Bristol.

CHESTER GENERAL INFIRMARY.—Assistant House Surgeon for six months. Salary at the rate of £40 per annum, with residence and maintenance in the house.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY, Wakefield.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

COUNTY ASYLUM, Whittingham, Lancashire.—Junior Assistant Medical Officer, unmarried. Salary commencing at £100 per annum, with prospect of increase, together with furnished apartments, board, attendance, and washing.

DONCASTER GENERAL INFIRMARY AND DISPENSARY, Doncaster.—Indoor Dispenser and Assistant to the House Surgeon. Board, lodging, and washing provided.

ESSEX AND COLCHESTER HOSPITAL, Colchester.—House Surgeon, single or widower without family. Salary £100 per annum, with board, residence, and washing at the hospital.

GUEST HOSPITAL, Dudley.—Resident Assistant House Surgeon, for six months. Salary at the rate of £20 per annum, with board, lodging, and washing in the hospital.

HANTS COUNTY ASYLUM, Farnham.—Third Assistant Medical Officer, unmarried. Salary £100 per annum, increasing to £125 after twelve months' service, with furnished apartments, board, washing, and attendance.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London.—Honorary Physicians and Honorary Surgeons.

HOSPITAL FOR WOMEN, Soho-square, London, W.—House Physician for six months. Salary £30 for that period. Also non-resident Clinical Assistant.

HULL AND SCULCOATES DISPENSARY, Parliament-street, Hull.—House Surgeon. Salary £200 per annum, with house (unfurnished), coals, and gas.

JOINT COUNTIES ASYLUM, Carmarthen.—Second Assistant Medical Officer, unmarried. Salary £100, increasing, if suitable, to £120, by increments of £10 at the end of the first and £10 at the end of the second year, with board, lodging, washing, and attendance.

LONDON THROAT HOSPITAL, Great Portland-street, W.—House Surgeon (non-resident) for six months. Salary £25.

METROPOLITAN ASYLUMS BOARD.—Assistant Medical Officer for the Eastern Fever Hospital, Homerton, N.E., unmarried. Salary, first year £160, for the second year £180, and for the third and subsequent years of service £200, subject to statutory deduction, with board, lodging, attendance, and washing. Applications to the Clerk to the Board, Norfolk-street, Strand, W.C.

PARISH OF ST. LEONARD, Shoreditch.—Medical Officer for the separate Infirmary, Hoxton-street, N., and for the adjacent Workhouse of the parish. Salary (apportioned between the Workhouse and Infirmary) either £300 per annum, with furnished apartments, board, washing, and attendance, or £400 per annum, with furnished apartments, lights, fire, and washing, subject to statutory deductions. Applications to the Clerk to the Guardians, Clerks' Offices Kingsland-road, N.E.

PRESCOT UNION.—Resident Medical Officer for the Workhouse and Infirmary at Whiston, unmarried. Salary £80 per annum, rising to £100 by annual increments of £10, with furnished apartments and residential allowances, subject to statutory deduction. Applications to the Union Clerk, Union Offices, Whiston, Prescot.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, Ventnor, Isle of Wight.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging in the hospital. Applications to the London Office, 34, Craven-street, Charing-cross, London.

SCARBRO' HOSPITAL AND DISPENSARY.—Assistant House Surgeon for six months. Salary at the rate of £50 per annum.

SCHOOL BOARD FOR LONDON, Victoria Embankment, W.C.—A Male and a Female Practitioner. Salary £250 per annum each.

SEAMEN'S HOSPITAL SOCIETY (Dreadnought), Greenwich, S.E.—House Physician. Salary £75 per annum, with board and residence. Applications to the Secretary, Greenwich.

ST. THOMAS'S HOSPITAL, London.—Assistant Physician.

TUNBRIDGE WELLS EYE AND EAR HOSPITAL.—Lady House Surgeon. Salary £60, and board and lodgings. Applications to the Honorary Secretary, 3, the Pantiles, Tunbridge Wells.

WARNEFORD HOSPITAL, Leamington.—House Surgeon for six months. Salary at the rate of £100 per annum, with board, lodging, and washing.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, Welbeck-street, W.—Honorary Surgeon.

WEST RIDING ASYLUM, Wadsley, near Sheffield.—Second Assistant Medical Officer. Salary £180, with board, &c., rising £10 annually to £230.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—House Surgeon, and to act as Surgical Registrar for one year. Salary £100 a year, with board, lodging, and washing. Also House Physician, and to act as Medical Registrar, Pathologist, and Anæsthetist, for one year. Salary £100 a year, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BOLUS.—On April 28th, at Beckenham, the wife of H. B. Bolus, M.B. Cantab., of a daughter.

CROUCHER.—On April 30th, at Onslow House, Burlington-place, Eastbourne, the wife of Alexander H. Croucher, M.D. Edin., of a son.

EVANS.—On April 27th, at Denmark Lodge, The Grove, Clapham-common, the wife of Lewis Evans, L.R.C.P. Edin., L.F.P.S. Glasg., of a daughter.

FERRABY.—On April 27th, at St. Mary-street, Ladywood, Birmingham, the wife of G. A. Ferraby, L.R.C.P., M.R.C.S., of a son (Arthur Ludovic).

GASTER.—On May 2nd, at Greencroft-gardens, West Hampstead, N.W., the wife of A. Gaster, M.D., M.R.C.P. Lond., of a son.

MANN.—On April 30th, at Newgate-street, Chester, the wife of Alfred Mann, M.D., of a son.

SEGUNDO.—On May 3rd, at Brook-street, Hanover-square, W., the wife of C. S. de Segundo, M.B., B.S. Lond., of a son.

MARRIAGES.

HARDING—WALTON.—On April 27th, at St. Peter's, Swinton, Lancashire, Charles Headley Harding, M.R.C.S. Eng., L.R.C.P. Lond., only son of the late C. F. Harding, M.D. Lond., of Whittlesea, Cambs., to Florence Ada, youngest daughter of Joshua Walton, Esq., of Kingslea, Swinton.

HINDLEY—TYLER.—On May 1st, at Southampton, Godfrey Douglas Hindley, B.A. Oxon., M.R.C.S., L.R.C.P., of Queen's-road, N.E., to Alice Evelyne, eldest daughter of Sir John Tyler, M.D., C.I.E., of Hanover-square, W.

JONES—PORTER.—On April 27th, at Wreay Church, T. Henry Jones, M.B., C.M., eldest son of Henry Jones, of Chester, to Edith Frances Porter, youngest daughter of the late W. H. Porter, of Heads Nook.

JOHNS—DICKINSON.—On April 26th, at Misson, John Francis Johns, M.D., of Lansdown-place, Cheltenham, to Lucie, third daughter of the late John Dickinson, Misson, Bawtry.

KNIGHT—MITCHELL.—On April 27th, at St. Andrew's Church, Bolton-on-Dearne, W. H. Knight, L.R.C.P., L.R.C.S. Edin., of Cudworth, near Barnsley, to Ellen Josephine May Mitchell, daughter of the late Joseph Mitchell, C.E., J.P., of Bolton Hall, Rotherham.

LANE—COGHLAN.—On April 27th, at Stepney Parish Church, by the Rev. John Hallward, Harry Argell Lane, M.R.C.S. Eng., D.P.H. Camb., third son of Thomas Argell Lane, of Holbeach, Lincs., to Mary, eldest daughter of John Coghlan, of Rathgar, Dublin.

LOVEDAY—WIX.—At the Abbey, St. Albans, William Dunmore Loveday, L.R.C.P., M.R.C.S., son of William Loveday, of The Poplars, Irthlingboro', Northants, to Lilian Emily, youngest daughter of the late Samuel Wix, of Broadwater Down, Tunbridge Wells, Kent.

SCOTT—MURRAY.—On April 28th, at the John Knox Presbyterian Church, Newcastle-on-Tyne, by the Rev. A. Scott Berrie, T. O. Scott, M.A., M.B., eldest son of the late Mr. John Scott, of Berwick-on-Tweed, to Elizabeth Stuart, eldest daughter of A. D. Murray, editor of the *Newcastle Daily Journal*. No cards.

THORNE THORNE—HOUGHTON.—On April 27th, at St. Peter's, Old Woking, by the Rev. F. J. Oliphant, M.A., vicar, assisted by the Rev. W. F. T. Hamilton, M.A., Berthold Bezly, eldest son of Sir Richard Thorne Thorne, K.C.B., F.R.S., to Ruth Golding, daughter of the late John Houghton, of Liverpool, and of Mrs. Houghton, of Poundfield, Old Woking.

DEATHS.

AUSTEN.—On May 2nd, at Matto'k-lane, Ealing, Josiah Austen, M.R.C.S., L.R.C.P., late Staff-Surgeon R.N.

GORDON.—On April 29th, at Hume-street, Dublin, Samuel Gordon, M.D., ex-President of the Royal College of Physicians of Ireland.

IRVING.—On May 3rd, at Royal York-crescent, Clifton, Bristol, Surgeon-General James Irving, M.D., Bengal Army (retired), aged 75 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.).

WEDNESDAY (11th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.).

THURSDAY (12th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.).

FRIDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (14th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.) St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (9th).—MEDICAL SOCIETY OF LONDON.—8 P.M. General Meeting for Election of Officers and Council for Session, 1898-99. 8.30 P.M. Ordinary Meeting. Mr. C. Mansell Moullin: The Treatment of Tuberculous Disease of the Bladder.—Dr. Macnaughton-Jones: Recurrent Hæmatemesis caused by Hepatoptosis discovered by Laparotomy.

TUESDAY (10th).—ROENTGEN SOCIETY (11, Chandos-st., W.).—7.30 P.M. Council Meeting. 8 P.M. Papers:—Mr. A. Apps: Notes on the Description of a New Induction Coil in *Electrical Review*, Feb. 4th, 1898 (with demonstration).—Dr. J. Macintyre: Some Notes on Contact Breakers. Followed by a discussion.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Dr. S. West: Intra-pleural Tension.—Mr. A. Doran: A Case of Cyst of the Urachus, with notes on Urachal and so-called Allantoic Cysts

WEDNESDAY (11th).—SOCIETY OF ARTS.—8 P.M. Prof. V. B. Lewes: Water Gas and its Applications.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by Dr. D. Grant, Dr. Pegler, Mr. Wingrave, Mr. Baber, Mr. Robinson, Mr. Walsham, and others.

THURSDAY (12th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Edgware-road).—8.30 P.M. Dr. M. Handfield-Jones: The Clinical Aspects of Cancer of the Body of the Uterus.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square).—8.30 P.M. Specimens will be shown by Dr. G. Bantock, Mr. F. Bowreman Jessett, Mr. W. D. Spanton (Hanley), Mr. J. F. Jordan (Birmingham), and Mr. C. Ryall. Dr. F. Edge: Notes of a Case of Uterus Septus Bilocularis and Vagina Subsepta. Paper:—Dr. F. Purcell: The Risks to the Ureters when Performing Hysterectomy, illustrated by a case in which both Ureters were Occluded and freed fifty-eight hours after. Discussion on Dysmenorrhœa (opened by Dr. G. Bantock).

FRIDAY (13th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. D. B. Lees and Mr. A. Q. Silcock: Case of Cæcal Intussusception, Excision of involved Gut, Recovery.—Dr. W. S. Colman and Mr. T. H. Kellock: Case of Chronic Intussusception of the Cæcum with extreme Latency of Symptoms.—Dr. D. B. Lees: Case of Chronic Intussusception treated by Irrigation and an Icebag, Recovery. Dr. H. D. Rolleston: Case of Perforation of the Vermiform Appendix in the Course of Ambulatory Typhoid Fever, Operation, Death.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

MONDAY (9th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. E. Woakes: Nasal Neurosis.

TUESDAY (10th).—ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Dr. S. M. Copeman: On the Natural History of Vaccinia. (Milroy Lecture.)

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abraham: Lichen Planus and Acuminatus.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Taylor: Lecture.

WEDNESDAY (11th).—LONDON POST-GRADUATE COURSE. — Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: Construction of Dwelling-houses.

THURSDAY (12th). — LONDON POST-GRADUATE COURSE. — Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. T. Williams: Clinical Lecture.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Waterhouse: Clinical Demonstration of Surgical Cases. (Post-graduate Class.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Barlow.

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Lantern Demonstration to Senior Students—Lung Disease.

ROYAL INSTITUTION.—3 P.M Right Hon. Lord Rayleigh: Heat.

LONDON SKIN HOSPITAL (40, Fitzroy-square, W.).—4 P.M. Mr. J. Startin: Rare Clinical Cases.

FRIDAY (13th). — LONDON POST-GRADUATE COURSE.—King's College 3 to 5 P.M., Dr. Wilkinson: Examination of Air, Soil, and Water.

ROYAL INSTITUTION.—9 P.M. Prof. W. A. Tilden: Recent Experiments on certain of the Chemical Elements in relation to Heat.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

UNREGISTERED PRACTITIONERS.

MR. LEOPOLD LEIBSTER was recently charged at Worship-street Police-court with having wilfully used the name and title of a Doctor of Medicine, he not being registered as a medical practitioner. His cards and plate bore the words M.D. Vienna, but he admitted to a patient who called on him at the instance of the prosecution that he could not give a certificate as he was not registered in this country. It was allowed that he was registered in Vienna. The magistrate dismissed the summons and gave defendant his costs, agreeing to state a case for a higher court. This being the case we refrain from any comment.

AN OPPORTUNITY!

To the Editors of THE LANCET.

SIRS,—The enclosed is a copy of a letter from a young cousin of mine in South Africa and is of course quite innocently written and well meant on his part. It may be thought worthy of more extensive circulation through your columns, free, gratis and for nothing, as Mr. Bone will not be distracted with a multitude of offers.

I am, Sirs, yours faithfully,

May 2nd, 1898. B.

[ENCLOSURE.]

March 27th, 1898.

MY DEAR C——,—There is a man here named Wm. Bone, a doctor who passed all his exams. except his final, consequently has no degree. He has been practising here for the last five years and was making about £800 a year, but now the Government have jumped on him and shut him up. If you have the necessary degree and care to come out and go into partnership with him you could work up the business to, say, £1500 per annum or more. It is very nearly a cash business, Dutch people and Kaffirs. If you think anything at all about it write to Wm. Bone. He will answer any question you care to ask, and I think would pay your passage, or at all events part of it. Yours, &c., ——.

*** We have thought it wiser to omit Mr. Bone's address.—ED. L.

CIGARETTES.

MESSRS. OGDEN of Cornwallis-street, Liverpool, have submitted to us specimens of their Guinea Gold Cigarettes which they claim to be of pronounced purity. We found that they were composed of light Virginia leaf and were quite free from objectionable flavouring materials.

THE GREAT GREGORY.

To the Editors of THE LANCET.

SIRS,—Can you tell me if the great physician who is commonly known and spoken of as "Gregory" is the same Gregory who wrote "Conspectus Medicinæ Theoreticæ," published in 1333? I shall be glad if you can oblige me with the desired information in the next issue of THE LANCET. Thanking you in anticipation,

I am, Sirs, yours faithfully,

May 3rd, 1898. M.B.

*** There have been three Gregorys eminent in the medical world, John, James, and William, but James is the great Gregory. John was Professor of Medicine in Edinburgh University about 1765 and wrote "Observations on the Duties of a Physician" and a popular didactic work in the shape of letters called "A Father's Legacy." James succeeded his father as Professor of Medicine at Edinburgh and wrote the "Conspectus Medicinæ Theoreticæ," the first edition of which was published in 1780. He was a magnificent teacher and lecturer and a keen controversialist. William, his son, also a medical man, worked chiefly at chemistry. He was Professor of Chemistry at Edinburgh, edited Liebig's "Animal Chemistry," and wrote one or two original treatises. He was inclined to mystic views on the subject of animal magnetism.—ED. L.

THE FIERY ORDEAL OF FIJI.

THE May number of the *Wide World Magazine* among other interesting articles dealing with travel and adventure contains a vivid account of a religious ceremony "which has hitherto baffled the scientists and astounded the traveller in the South Seas." The ceremony, according to the writer, takes place in the island of Benga, the supposed residence of some of the old gods of Fiji. A circular oven is dug in the ground, measuring some 18 ft. or 20 ft. in diameter and lined with large water-worn stones which are made white-hot by means of a wood fire. So great is the heat that anyone but a native finds it intolerable to stand 10 ft. from the edge of the oven. The ceremony consists of the performers walking about bare-legged and barefooted on the hot stones. It has been suggested that the natives are able to perform this feat because they have on the soles of their feet a natural sort of leathery substance which is a non-conductor of heat. But, says the writer, Lord Stanmore has stated that he has seen the natives while crossing a short extent of the shingly bed of a river in the hot sunshine compelled to rush into the stream to cool their feet.

"THE JOHN PAGE HENTSCH APPEAL"

To the Editors of THE LANCET.

SIRS,—Subjoined is a further list of contributions to this fund:—Mr. H. H. Clutton, F.R.C.S. Eng., £2 2*s.*; Dr. W. F. Brooke, £1 1*s.*; and Dr. de Havilland Hall, £1 1*s.*—I am, Sirs, yours faithfully,

410, Brixton-road, S.W., May 3rd, 1898. G. DAVID KNIGHT.

A LADY FACTORY INSPECTOR CONDUCTING HER OWN CASE.

ON April 29th a dressmaker of Wellington-street was summoned under the Factories Act for omitting to notify that some of her employées were working overtime and for failing to post overtime notices in the workshops. Miss Dean, the lady inspector, appeared and gave evidence in support of the charges. The defendant through her solicitor pleaded guilty and evidence having been given that this was by no means the first offence the magistrate fined the defendant in all £19 17*s.* 6*d.*

THE CHURCH HOUSE CHILDREN'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—About three years ago the birth of the society I founded was made known by a letter to the *British Medical Journal*. The principle of the scheme was the training of ladies in the means of reducing infantile mortality, the attachment of them to out-patient departments and their following up of infant patients by visits and instruction to the mothers in their own homes. After I left the Bristol Children's Hospital I tried to get the hospitals of Bristol to accept the services of my workers. For reasons best known to the institutions they refused and finding that in order to get access to the homes a dispensary was necessary I established one where nurses attended and followed up infant patients with necessary home supervision. Several distinguished specialists in children spoke highly of the scheme which I made known at various London hospitals at the outset. The society grew until a large building was taken and wards were furnished. This was advertised eight months ago and since then 800 new patients have been admitted and have been seen on an average seven or eight times each. Ten in-patients have been cared for and several operations have been done. There are two nurses on active duty and I reside on the premises. There are five beds and one in-patient—a charity case—under constant care for chorea. The most of the money that supports the institution comes from fees arranged on a sliding scale to suit the patients, but forty subscribers' notes have been given away and 78 patients have been treated fully by me without fee or subscriber's note. Lectures on nursing are given and the ladies of the society make clothes and provide medical comforts and even milk for starving or very poor infants. The work is surely a noble one and in this crowded industrial centre a hospital is much needed. None of the workers are paid and no salary is allotted to me by the society. If a resident surgeon, two nurses, and a large building with twelve rooms and five available beds is a hospital then surely I have not erred in giving for the first time to the public what has been privately known for several months as the Nursery Aid Society's Cottage Hospital or Church House Children's Hospital. I am pleased to see that the Belgrave Children's Hospital is now about to begin lectures to nursery maids, but I believe when I began our Nursery Aid Society in August, 1895, at the Bristol Children's Hospital we were the first to insist on the great need of sending skilled nursery aid instruction into the actual homes of the people.

I am, Sirs, yours faithfully,

W. L. CHRISTIE.

The Church House Children's Hospital, May 3rd, 1898.

"ET DONA FERENTEM."

"Professor Munyon has, by cable, offered £100,000 worth of his medicines as his patriotic contribution to the United States Army and Navy."

We extract this item of information from the *News of the World* for May day and are wondering where the patriotism comes in.

Medicus.—Vaccination fees are reckoned as "emoluments" if the district medical officer is holding the appointment of public vaccinator at the time when he resigns the post of medical officer. Superannuation will be calculated, in our opinion, with reference to both district appointments and will vary in amount proportionally to the length of time that the holder has been in possession of the posts. This is a matter of opinion only. Until such points have been actually and officially decided it is not possible to answer with absolute certainty. Vide THE LANCET, vol ii., 1896, p. 1167.

J. A. R.—Our correspondent could not do better that use the popular form which he is told "is out of date." In our opinion it is the best form. We do not give reasons, for we do not pretend to be specialists in the mechanism of cycles; we only speak with regard to matters of health when such matters are in any way touched upon in relation to cycling.

Mr. A. Wright.—Public vaccinators are not mentioned by name under the Poor-law Superannuation Act of 1897, but in our opinion they do come under its provisions all the same. Our correspondent will find the matter fully dealt with in a leading article published in THE LANCET of Nov. 7th, 1896.

M.D. has not complied with the rule that correspondents must furnish their names and addresses.

Verax.—Our correspondent's communication will receive detailed attention next week.

Aqua.—We have no information.

Mr. M. Romey.—Yes.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière Amières Paris.

The Milroy Lectures

ON

THE NATURAL HISTORY OF VACCINIA.

Delivered before the Royal College of Physicians of London on May 3rd, 5th, and 10th, 1898,

BY S MONCKTON COPEMAN, M.A., M.D. CANTAB., M.R.C.P. LOND.,

MEDICAL INSPECTOR TO HER MAJESTY'S LOCAL GOVERNMENT BOARD LECTURER ON PUBLIC HEALTH IN THE MEDICAL SCHOOL OF WESTMINSTER HOSPITAL.

LECTURE II.[1]

Delivered on May 5th.

MORPHOLOGY AND CHEMISTRY OF VACCINE LYMPH.

MR. PRESIDENT, CENSORS, AND GENTLEMEN,—Fresh vaccine lymph, taken before full maturity of the vesicle, is a clear, transparent, limpid fluid, almost colourless in man and slightly straw-coloured when obtained from the calf; this difference in colour depends on the varying quality of the normal pigment present in the blood plasma. Calf vaccine lymph is also somewhat more viscid than human lymph and does not flow so readily when the vesicle is punctured; for which reason it is necessary to use compression forceps in the ordinary methods of collection of calf lymph. Examined microscopically vaccine lymph contains a certain amount of epithelial débris, a few cells and portions of cells being always visible. Leucocytes are usually present also, the number depending on the stage at which the lymph is taken; few or even none are to be found in the contents of the vesicle when first formed, but at or after the period of maturation they may be so numerous as to render the lymph turbid or even puriform. A few red blood corpuscles may be noticeable, although most observers will hardly agree with the statement made by Dr. W. Husband to the Royal Commission on Vaccination that this is invariably the case. In stained specimens, particularly, micro-organisms of one or more varieties can readily be demonstrated, the actual numbers being dependent to a certain extent on the care with which the lymph has been collected. The nature and significance of the various microbes which at one time or another have been isolated from specimens of vaccine lymph will be discussed in the section on bacteriology.

It is matter of common knowledge that untreated lymph when stored in capillary tubes tends after a longer or shorter interval to become cloudy, under which circumstances it is also liable to be uncertain in its action if subsequently used for the operation of vaccination. This opaque appearance may be quite independent of any coagulation of the lymph, as may not unfrequently be demonstrated on breaking tubes in which it is most marked. On the other hand, where clotting has taken place after the lymph has been stored, the opacity tends to form with the coagulum a central whitish thread in the midst of a clear fluid, instead of being distributed through the lymph in discrete points as may otherwise be the case. If cultivation experiments be carried out by inoculation on nutrient media the number of colonies resulting from such inoculation with the contents of tubes which have become opaque is usually much greater than if fresh lymph is employed in a similar manner. We are apparently justified, therefore, in considering that the opacity of such old stored lymph is, in the main, the outcome of an enormous multiplication of aerobic bacteria the ancestors of which are present in the lymph when first collected, although their numbers are then so comparatively small as not to render it in any way turbid. It follows that ordinary vaccine lymph which has become opaque should never be employed for vaccination. Vaccination lymph, chemically speaking, consists of the serum or rather of the plasma of the blood. When freshly obtained, therefore, it is faintly alkaline in reaction, but it tends to become distinctly acid after a time when stored. In addition to the various salts and proteids normally present in the blood plasma vaccine lymph contains some substance, possibly of the nature of a toxin or ptomaine, which results from the vital activity of the specific organism peculiar to vaccinia. That this is so may be proved either by filtration of the lymph through porcelain or by exposure of it to a temperature of about 50° C. If, as I have shown, such filtered or sterilised lymph be inoculated on the skin in the usual manner no obvious effect is produced at the point of inoculation, but it will be found that the animal has been rendered temporarily immune to the effects of subsequent vaccination with lymph of normal potency.

BACTERIOLOGY.

Although the study of the bacteriology of vaccinia and variola has, during the past thirty years or so, attracted the attention of a great number of observers, much yet requires elucidation before we can look upon our knowledge in this direction as satisfactory. Nevertheless progress though slow is perhaps sure, and it would seem as if it must be the very difficulties of the subject which enhance the inducement for the constantly renewed initiation of investigations by observers in all parts of the world. As long ago as the year 1809 Sacco placed on record the fact that in vaccine lymph there might be found certain granules generally collected together into masses and possessed of the power of automatic movement. The observation appears to have stood alone for more than half a century, but in 1863 Dr. Lionel Beale gave an impetus to the investigation of the morphological constituents of vaccine lymph by his description of the existence in it of transparent or hyaline particles of extreme minuteness. Both in his original paper in the *Microscopical Journal* for April, 1864, and also subsequently in the Report of the Royal Commission on the Cattle Plague, Dr. Beale expressed the opinion that these granules constituted the contagious principle of the disease, but he does not appear to have obtained experimentally any facts in support of his belief. A few years later Hallier and Zurn (1867) and Keber (1868) called attention to the presence in vaccine lymph of numerous micrococci, or "grains" as they were termed by the latter observer, who also evidently regarded the bodies found by him as the carriers if not the actual generators of the virulent principle.

It is, however, to M. Chauveau (1868) and Professor Burdon Sanderson that we owe the first real step toward the elucidation of the micro-pathology of vaccinia, these observers having demonstrated that vaccine lymph when freed from its contained particles and inoculated on a living animal no longer causes vaccinia, while, on the other hand, the precipitate or deposit, separated from it in one way or another, when employed in similar fashion remains capable of producing the disease. M. Chauveau found that vaccine lymph taken at the stage of maturation of the vesicles contained minute granular bodies to which he gave the name of *corpuscles noirs*, and not unfrequently also much larger bodies resembling the leucocytes of pus. He further found that if the lymph was diluted ten times and allowed to stand these leucocytes when present gradually subsided to the bottom of the containing vessel and could then be removed. When this was done and the material employed for an experimental vaccination a local result was still obtained, thus showing that the active principle was contained not in these leucocytes but either in the granules or in the fluid portion of the lymph. In order to settle this point M. Chauveau devised a method of diffusion by which he was eventually able to separate the granules from the fluid portion of the lymph. The amount of vaccine lymph at his disposal being necessarily exceedingly small the ordinary means for obtaining diffusion were not applicable. M. Chauveau attained the desired object, however, by carefully floating a layer of distilled water on to the surface of a drop of lymph contained in a tiny glass vessel of cylindrical shape. If this manipulation is dexterously performed the two liquids do not mix with each other excepting in the immediate neighbourhood of the point of junction (of the two layers). But after a time the soluble constituents of the vaccine lymph pass upwards into the water, so that if after 24 hours or so a portion of the upper layer be carefully removed by means of a capillary tube and examined under the microscope it is found to be free from "granules." And, further, M. Chauveau was enabled to demonstrate the fact that while this upper layer of fluid which could be shown to contain albumin and so afforded evidence of diffusion having taken place, gave negative results only on inoculation, the lower layer, on the

[1] Lecture I. was published in THE LANCET of May 7th, 1898.

contrary, which contained the "granules" in suspension, was found to be active as vaccine, normal vesicles being obtained as the result of its inoculation Professor Burdon Sanderson shortly afterwards repeated M. Chauveau's work, employing certain improvements in the method which seemed likely to render it more accurate and thus to afford results of greater scientific value. He also made use of another method of his own consisting in the filtration under pressure of the liquid to be tested through a layer of unglazed porcelain, by which means all solid particles were effectually separated from the fluid containing them. Professor Sanderson, by the employment of this method and also of his modification of that originally introduced by M. Chauveau, fully confirmed the results announced by the French investigator. Further, M. Chauveau, by largely diluting vaccine lymph with distilled water and employing the mixture for vaccination, found that he thus obtained strong additional evidence in support of the doctrine now universally accepted that contagium is particulate in nature. He was enabled to show that whatever the degree of dilution the local effect produced (provided that it is produced at all) is always the same. In other words, the difference between the effect of inoculating extremely diluted lymph and that of inoculating the lymph itself without any addition of water does not manifest itself, as might be expected, in the size of the individual vesicle or vesicles produced. He found, on the other hand, that the difference consisted entirely in the numerical relation of successes to failures. If successful, inoculation with a liquid containing an extremely small proportion of lymph may communicate the disease as completely as the original lymph itself—a result which is not only perfectly consistent with the fact that contagium is particulate, but which is in itself a necessary consequence of its being so. As bearing on this question it may be mentioned that Schultz of Berlin has quite recently been engaged in an investigation having for its object the determination of the extent to which, in order to save time and expense, glycerinated vaccine lymph could be diluted without losing its efficiency as vaccine. In the course of his experiments he found that an emulsion containing one part only of vaccine pulp in 2000 parts of glycerine and water was capable of producing locally a normal vesicle in a small proportion of the cases in which it was employed for vaccination. The experiments of Reiter confirmed those of M. Chauveau and showed that vaccine lymph even when excessively diluted was capable of affording a positive result on vaccination, provided the more extensive the dilution the greater the absorbing surface. In 1872 a paper was published by Cohn of Breslau in which he treated the morphological aspects of the subject with much completeness. His observations, which related to both vaccine lymph and variolous lymph, have received general corroboration from all subsequent workers. He, however, apparently believed certain micro-organisms found by him to be of one species only, to which accordingly he gave the name micrococcus vaccinæ or variolæ as the case might be, whereas later observers have shown that organisms of more than one species are usually to be found in any given specimen of crude lymph. Cohn called attention to the fact that in perfectly fresh vaccine lymph the "corpuscles" for the most part occur singly, but that others are joined together in pairs in a form resembling the figure 8; and he states that after the lymph has been kept for a time the number of the "double cells increases and soon chains of four begin to be distinguishable. These chains are usually curved or in zigzags; their attachment one to another is evidently very slight as they can readily be displaced. After a few hours' observation they are seen to be all aggregated into irregular colonies or clumps, each consisting of sixteen, thirty-two, or more corpuscles." He also noted a point of importance in connexion with the opacity which is apt to occur in stored lymph—namely, that "in capillary glass tubes the enlargement of colonies sometimes lasts a long time so that groups of them acquire considerable size and present themselves as floccuii."

Klebs (1873) isolated from vaccine lymph micrococci united together in the form of tetrads which he considered as specific and to which he gave the name of tetracoccus vaccinæ. Cornil and Babes (1883) also met with micrococci. Koch (1882) found micrococci in the vaccine vesicles of a child and noted that human lymph freshly prepared with glycerine contained what he appears to have regarded as the specific bacteria of vaccine. These developed but slowly even in the incubator and were met with in fewer numbers in old lymph, even though it still remained active. Quist in the following year (1883) published a series of experiments dealing with the possibility of cultivating outside the animal body the micro-organisms present in vaccine lymph. The culture fluid employed by him was composed of equal parts of blood-serum, glycerine, and distilled water, this mixture being rendered alkaline by the addition of $\frac{1}{100}$ part of carbonate of potash. After sterilising this fluid by exposing it to a temperature of 60° C. for one and a half hours on three successive occasions it was inoculated with a minute piece of sterilised sponge soaked in clear lymph or with a piece of vaccine "crust" which had been washed in distilled water and then carefully dried. He found that growth eventually occurred both on and below the surface, the former consisting of minute scales while the latter gradually settled to the bottom of the vessel as a fine sediment. The scales, forming a scum on the surface of the fluid, he found to be composed of swarms of micrococci which, when inoculated on the skin of calves, in some cases gave rise, in his opinion, to a typical eruption of vaccinia. Although Quist did not attain any great measure of success in the immediate object of his inquiry (the identification of the vaccine organism), still he showed that the specific contagium of vaccinia could exist for a time at any rate in a fluid containing a considerable portion of glycerine.

About this same time papers were published by Feiler (1883), Serebriakoff (1884) Baragi (1884), and Hubert (1884), all of whom denied that vaccine lymph contained any specific microbe whatever. Voigt isolated three species of bacteria by making gelatin plate cultures of vaccine lymph. Of these one, which alone was constantly to be found, he considered to be specific and consequently termed it the vaccinococcus. He describes this as a small coccus growing usually in groups of two or four, sometimes in masses and less often in chains. These bacteria gave rise to glistening white circular colonies which did not liquefy the gelatin in which they were grown. He further stated that cultivations of this bacterium when inoculated on calves rendered them immune to subsequent vaccination. Guttman (1886) also found three micrococci in the contents of vaccine vesicles. These were the micrococcus pyogenes aureus, micrococcus pyogenes albus, and micrococcus viridis flavescens, but none of these is specific to vaccinia. Marotta (1886) found a coccus (micrococcus tetragonus) which he regarded as specific. By its use he thought that he had succeeded in producing vaccine vesicles. From the characters which he assigns to his cultivations it would appear that in reality what he isolated was the staphylococcus pyogenes aureus. In 1886, Meguin called attention to the fact that the number of micrococci contained in vaccine lymph increased considerably from the second day onwards after the removal of the lymph. During the same year (1886) Dr. Buist succeeded in isolating from vaccine lymph three varieties of micrococci which when grown on nutrient media gave rise to colonies of a white, yellow, or orange colour respectively. All these Buist appears to have considered to be essential constituents of vaccine lymph, as is evidenced by the fact that he speaks of them as white, yellow, or orange vaccine respectively. From specimens of variolous lymph he succeeded in obtaining one organism only, the colour of which was white when grown on solid media. With none of these cultures did he obtain any definite result on the inoculation of calves, monkeys, or human beings.

A certain small measure of success appears to have attended inoculation experiments in the hands of Carmichael (1887), who does not, however, give any detailed description of the morphological characteristics of the growths which he obtained, which, by the way, although differing from one another in colour, he seems to have considered to be the product of one species of micrococcus only. As was doubtless the case with Quist's experiments, in the few instances in which true vaccine vesicles resulted at the site of his inoculations, success was in all probability due to the presence in the material employed of a small proportion of the lymph originally used for the seeding of his culture medium. Tenholt (1887) appears to have isolated from specimens of vaccine lymph a dozen different micrococci, two bacilli, and two yeasts. Hlava (1887), on the other hand, isolated from vaccine vesicles the streptococcus pyogenes, the staphylococcus pyogenes, the staphylococcus pyogenes albus, the staphylococcus cereus albus, and the micrococcus viridis flavescens. Garré (1887) reported the existence in vaccine

lymph of two bacilli and of a small coccus which he considered to be specific; this, when inoculated on the calf, produced the vaccinal eruption followed by immunity, while in the human being it afforded immunity although giving rise to no eruption. Pfeiffer, a year later (1887), recorded the existence in vaccine lymph of micro-organisms of several different forms, including a yeast (named by him saccharomyces vaccinæ) two sarcinæ (lutea and aurantiaca), a short bacillus allied to proteus vulgaris but differing from it in not being pathogenic, and certain micrococci of which one, the staphylococcus cereus albus (Passet) was of constant occurrence, while the staphylococcus pyogenes aureus and albus were less frequently met with. Pfeiffer, however, believes that the specific agent of variola and vaccinia is not to be sought for among the bacteria but rather that it belongs to the class of sporozoa. This subject will require further notice later. In addition to the staphylococcus aureus and albus M. Grigorieu (1889) describes a micrococcus vaccinæ as specific to the disease. This microbe usually developes as a diplococcus, rarely forming chains, and grows slowly on gelatin which it liquefies after from four to six weeks. On the calf it produced a papular eruption which apparently afforded immunity to subsequent vaccination. M. Woitow (1890) succeeded in isolating four staphylococci—aureus, albus, cereus, and citreus. He affirms that the inoculation of a mixture of these microbes produced typical vaccinia in the calf. Professor Leoni (1890) met with several pyogenic microbes in fresh vaccine lymph, notably the staphylococcus pyogenes albus, which was invariably present. M. Protopopoff (1890) in like manner found it possible to isolate several different forms of micrococci.

As the result of my own work previous to 1891 (in which year my first paper was published) it would appear that there are at least three species of micro-organisms—namely, staphylococcus albus, staphylococcus pyogenes aureus, and staphylococcus cereus flavus, corresponding probably to Buist's white, orange, and yellow vaccine respectively—one or more of which are almost universally to be found in every specimen of human or calf vaccine lymph examined. Of these the staphylococcus albus is usually to be found in the upper layers of healthy skin of unvaccinated persons. In addition I have been able to satisfy myself as to the occasional presence of the streptococcus pyogenes. I myself have never detected the streptococcus of erysipelas, but Dr Klein has placed on record the fact that in one instance he isolated this microbe from a specimen of human vaccine lymph the use of a portion of which was believed to have given rise to the occurrence of erysipelas in the human subject. Also I have shown that none of the microbes ordinarily to be isolated from vaccine material can be regarded as specific to vaccinia. Professor Crookshank (1891) succeeded in isolating from various specimens of vaccine lymph—by the method of plate cultivation—an immense number of bacteria, including micrococci, bacilli, torulæ, &c. All of these he recognises as well-known saprophytic bacterial forms associated, some of them, with processes of suppuration, but none of which, he says, can be regarded as the contagium of vaccinia seeing that no single one of them is constantly present in vaccine lymph, human or bovine. M. Besser (1893) found in the papules of a case of small-pox at the fifth day a small bacillus which he is disposed to look upon as the specific organism of variola. He obtained cultures on various nutrient media, coverslip preparations from which always showed the organisms arranged in palisade-like rows. The late Professor Straus (1893) found that the seeding of gelatin plates with fresh vaccine material, whether glycerinated or not, gave rise to the appearance of numerous colonies of micrococci, among which the staphylococcus pyogenes aureus and albus were most frequently met with. When glycerinated lymph which had been kept for a considerable period was employed in similar fashion the number of colonies was greatly diminished. The paper, in which he collaborated with M. Chambon and M. Ménard, is illustrated with three figures of plate cultures from vaccine lymph which had previously been stored for different periods of time. M. Anthony (1893) in the course of the examination of a number of different specimens of vaccine lymph—glycerinated and otherwise—found that four different kinds of micrococci and three species of bacilli are apt to be present. Of these what he terms from its appearance the porcelain micrococcus is invariably present in fresh vaccine. The other three micrococci included the staphylococcus pyogenes aureus, a greyish white micrococcus liquefying gelatin, and a yellow micrococcus often present which does not liquefy gelatin and which grows easily in peptone beef broth, on gelatin, and on agar. The four bacilli noted by him include the bacillus subtilis, the bacillus mesentericus, a fluorescing bacillus, and a motile bacillus which grows in the form of yellow colonies. All these bacilli, according to this observer, represent impurities of the lymph. As the result of his researches M. Anthony concludes that vaccine lymph cannot be regarded as above suspicion as long as it is found to contain any microbes other than the porcelain micrococcus. The inoculation of cultures of his porcelain bacillus on heifers afforded only negative results. M. Maljean (1893) published a paper in which he describes the occurrence in vaccine lymph of two yellow cocci, of which one liquefies gelatin and the other does not, and of a peculiar micrococcus which is of a brilliant white colour when grown on various media and to which he gives the name of *coccus vaccinal;* this micrococcus is larger than streptococcus pyogenes and in cultures it grows as isolated points, as diplococci, and in short chains. Maljean states that this coccus gave rise in the guinea-pig to the formation of a suppuration and on the calf to a typical vaccine eruption. Other observers, however, employing the same cultures failed to obtain a positive result.

Dr. Klein agrees with me in maintaining that none of those microbes which ordinarily can be cultivated from vaccine lymph are "an essential inhabitant in vaccine" or "can have anything to do with its active principle." In the report of the medical officer to the Local Government Board for 1892–1893 he, however, described a peculiar, extremely minute bacillus as occurring in calf lymph and in variolous lymph of human origin obtained in an early phase of the disorder, in calf lymph from 72 to 96 hours after vaccination and in human variola during the third or fourth day. In both instances the lymph was collected aseptically. Clear lymph only, as free as possible from epidermal débris was used for film specimens, which, after heating and treatment with 30 per cent. acetic acid for some minutes, were subjected to prolonged staining in alcoholic gentian violet. Some of the films of calf lymph (collected after removal of the epidermis as a whole) showed an abundance of these minute bacilli, generally massed together, some of the specimens looking indeed like film specimens of an artificial culture. Lymph of early human variolous vesicles showed similar bacilli, but not so abundantly. Calf lymph taken at later stages (five or six days old) showed no bacilli or only a few here and there. In certain of these bacilli from vaccine lymph Dr. Klein succeeded in demonstrating spore-like bodies which, together with the absence of the bacilli in the lymph of later stages, led him to the conclusion that disappearance of these bacilli from the lymph was possibly the result of their having broken up after the formation of spores, which might alone be present about the time of maturation of the vesicle. Dr. Klein adds that these bacilli are incapable of cultivation in the ordinary culture media, no growth whatever having been obtained by him on solidified blood serum, glycerine agar, ordinary agar, sugar gelatin, or ordinary gelatin, although in specimens of the same lymph as was employed for this purpose, and which on transference to the calf produced perfect vaccine vesicles, bacilli were found in abundance. MM. Baillard and Anthony (1894) have worked at the question of the number of microbes present in vaccine which has been stored for various periods. Baillard constantly found in the lymph a white staphylococcus, a yellow staphylococcus, and bacillus subtilis. His experiments led him to the conclusion that, by keeping, the number of germs contained in glycerine pulp becomes considerably diminished, but that germs never completely disappear. After as long a time as seven months the material with which he was experimenting still contained some living germs, among which were the bacillus subtilis and staphylococcus albus. Leoni (1884) also experimenting on the effect of glycerine in the purification of vaccine lymph found that the microbes usually had disappeared in from one to four months. Dr. Buttersack (1894) described the appearance in vaccine lymph, dried on cover glasses, of a dense network of threads associated with numerous granules which he considered as peculiar to vaccine. These threads he regarded as the growing vegetative part of a vaccine fungus, the granules in his opinion representing spores. It appears fairly certain, however, that what he believed to be a mycelium with spores in reality consisted merely of threads and granules of fibrin or of some

other albuminous substance. In this same year (1894) I published a description of numerous minute bacilli sometimes to be found in considerable numbers in the vaccine vesicles both of the calf and the human being at an early stage of their development, in this respect apparently confirming the experience of Dr. Klein which was published in the same year, and of which mention has already been made. Similar bacilli were also demonstrated by Mr. Kent and myself in sections of skin passing through the site of a vaccine vesicle obtained from the calf.

An account of certain experiments dealing with the possibility of cultivating these micro-organisms and also a similar one isolated from variolous material I propose referring to later. M. Ruete (1894) obtained what he believed to be pure cultures of the specific agent of vaccine from calf lymph, this consisting of a micrococcus, the toxin elaborated by which he termed vaccinin. He failed, however, in his attempts at inoculation of the human being. In 1895 Landmann found that in Germany no less than 80 per cent. of certain children vaccinated successfully presented an excessive inflammatory condition of the arm, sometimes of an erysipelatous or hæmorrhagic character. In searching for the cause of these unfortunately numerous complications Landmann undertook an elaborate study of the lymphs distributed from 13 of the German institutes. As a result of his research he found that the number of germs present in the various specimens of lymph varied from 50 to no less a number than 2,500,000 per cubic centimetre. Among the microbes which he succeeded in isolating were the streptococcus pyogenes, the staphylococcus albus, and the staphylococcus aureus. Two American observers, Dr. Stephen C. Martin and Professor Ernst, recorded in 1895 the isolation of a micro-organism which they considered to be specific to vaccinia. This was a short, thin bacillus which they found was capable of growth on serum obtained from ox or horse's blood but not on other media. The growth, which is of a white colour, forms chains and under certain circumstances, according to these observers, takes on the form of a micrococcus. With a cultivation of this microbe of the fourteenth generation they produced a vaccine vesicle on an infant in one attempt out of ten, better success, however, attending their attempts at inoculation of a calf. M. Le Dantec in the same year (1895) found in lymph, staphylococci, the reactions of which he says shows that they are related to the ordinary pus cocci. These staphylococci differed according to the species of animal from which they were obtained, those isolated from calf lymph liquefying serum, while those obtained from human lymph did not do so.

M. Arloing (1896) experimented with the lymph of vesicles of horse-pox obtained by injecting a colt intravenously with vaccine lymph purified as far as possible by storage in glycerine. From the resulting vesicles he first carefully removed the superficial layer of epidermis and then collected the underlying material with aseptic precautions. With this he inoculated tubes of glycerine beef broth, obtaining as a result in each instance a growth consisting of a micrococcus which, however, when inoculated in turn on the animal body produced neither an eruption nor immunity to subsequent vaccination. From his researches M. Arloing concluded that the virulent agent of vaccinia must be of the nature of a soluble toxin. M. Boureau and M. Chaumier, also in 1896, found a number of different microbes in specimens of vaccine lymph, including staphylococcus aureus, cereus and albus, micrococcus flavus, bacillus subtilis and luteus, bacterium termo, proteus vulgaris, a cladothrix, a fluorescing bacillus, and several other bacilli, which they were unable to identify. They make the extraordinary statement that it is only when the vaccine has lost its virulence that the microbes originally contained in it completely disappear; that, in fact, the number of staphylococci present at any given time afford a measure of the potency of the lymph.

Dr. Saint-Yves Ménard (1896), in reply to this communication, reiterated the contention of Straus and himself, confirming my previous work on this subject, that the microbes which can be isolated from vaccine lymph by the ordinary methods are in no way essential to its specific action and that by the end of six months, at any rate, no micrococci can be obtained from "glycerinated emulsion," which has been preserved in sealed tubes, although it is still perfectly active as vaccine. Dr. Sacquépée (1896), in the course of examinations of various samples of vaccine lymph, met with three species of staphylococcus: the bacillus subtilis, the bacillus mesentericus, and another unknown species of bacillus. Of these he regards the bacillus subtilis and the bacillus mesentericus as evidences of accidental impurity of the lymph. Delobel and Cozette (1896–97), collaborating with Gourny, in common with most other observers, found that the bacteria most constantly present in vaccine lymph are a white and yellow micrococcus. They state that when due care is not exercised in the collection of the lymph, bacillus subtilis and bacillus mesentericus may be found. Inoculation experiments on the human being and on the calf afforded them only negative results. M. Paul, also in 1896, published a voluminous account of his researches on the occurrence and significance of pathogenic micro-organisms associated with vaccine lymph. He lays stress on his observation that the staphylococcus pyogenes aureus is by far the most ubiquitous of the microbes that are found in vaccine lymph, although it is certainly not an essential concomitant. He finds, moreover, that it exhibits both variable resistance and variable virulence. A sample of lymph, for instance, of supposed Jennerian stock he found to contain this staphylococcus in a phase of much higher virulence and resistance than was a specimen of this same microbe obtained from a sample of calf vaccine lymph. This staphylococcus, he adds, may be present without causing suppuration, but the use of a lymph containing it in large quantities should naturally be avoided. According to this observer the number of bacteria present in fresh lymph appears to be independent both of the origin of the stock from which it is derived and of the method of vaccination employed. This, as shown elsewhere, does not accord with my experience. Quite recently (1897), in conjunction with Dr. Blaxall, I have carried out a further extensive series of investigations on the bacterial flora of calf vaccine, with the outcome that, as the results of former work had led us to anticipate and as has been repeatedly shown by other observers, calf lymph (or, rather, vesicle pulp) may contain a large number of micro-organisms which are in no way concerned with its specific activity. Human lymph, as a rule, we find to contain remarkably few microbes, but probably this might not be the case were the whole substance of the vesicle removed, as is now usual in collecting from the calf. We have shown also, as have other investigators, that lymph, if carelessly collected, is often found to be contaminated with many of the numerous saprophytes common to dust, &c., in addition to certain possibly pathogenic microbes which may be present.

On the other hand, lymph taken directly from calves vaccinated with vaccine material rendered free from extraneous organisms, as, for instance, glycerinated lymph a month after emulsification, often presents remarkably few colonies of "extraneous" organisms. In one such sample only four colonies appeared on a plate culture of the lymph, one of staphylococcus cereus albus and three of a light brown yeast. If a vaccine vesicle of a healthy child or calf be carefully opened at an early stage with all aseptic precautions and a droplet of the lymph which exudes from it be submitted to bacteriological examination it may not unfrequently be found, as Dr. Klein has also demonstrated, that such lymph is absolutely pure in the sense that it contains no micro-organisms which will grow on ordinary culture media. Yet it is perfectly efficient as vaccine. But, on the other hand, as just stated, in lymph obtained in ordinary fashion from mature vesicles inoculation of plates or tubes of nutrient material usually results in abundant growth of micro-organisms. Those most commonly met with are, morphologically and culturally, identical with the staphylococci found in pus—viz., the staphylococcus aureus, albus, cereus albus, and cereus flavus. Of these the first two liquefy gelatin, the other two do not. Occasionally the streptococcus of pus may be present, as also the staphylococcus citreus. Other microbes of a purely saprophytic nature that are met with include the common hay bacillus, bacillus mesentericus, varieties of proteus, yeast moulds, and sarcinæ. These, however, can for the most part be excluded by careful manipulation, so that in vesicle pulp which has been collected with all due precautions nothing is found beyond some one or more of the four first-named staphylococci, of which a white staphylococcus is perhaps most common, and possibly one or more yeasts. Thus our most recent experience confirms in all essential particulars my first report published in 1891.

The fact that in vaccine lymph or in the vesicle pulp micro-organisms are found which, under certain circumstances, are known to be provocative of suppuration does

not in any way imply that the lymph in which they are present is purulent or that if such staphylococcus-infected lymph were employed for vaccination in the human being suppuration would necessarily ensue. The recent Berlin Commission, indeed, reports that of 18 samples of lymph examined, only 5 contained staphylococci which were pathogenic for small animals and, further, that no harm resulted on the vaccination of children with these particular specimens of lymph. From this circumstance it is evident that the virulence of these micro-organisms for rodents, for instance, cannot be accepted as a measure of their power to affect injuriously the body tissues in the healthy human subject. The streptococcus of pus must be a rare inhabitant of calf lymph, the Berlin Commissioners, indeed, stating that they never once met with it in the course of the examination of 64 samples of lymph. In human lymph it is by no means of so unfrequent occurrence. With reference to the question of the possible presence of the tubercle bacillus in lymph I am not aware of any authentic record of its having been found even in lymph derived from the calf. But, as I shall presently have occasion to show, we are enabled, by the use of a special method of preparing and testing vaccine lymph, to obviate any possibility of danger to which the presence of the tubercle bacillus or other pathogenic microbes in the original specimen of lymph might conceivably give rise.

In 1894, as already mentioned, I showed, concurrently with Dr. Klein, though independently, that in specially stained specimens of vaccine lymph taken at a period antecedent to full maturity of the vesicles the presence of bacilli of extremely small size and in practically pure culture can be demonstrated. These bacilli cannot be found, or only with difficulty, in mature lymph, for the reason probably that they have by then given place to spores. For some time it appeared impossible to obtain further evidence as to the *rôle* of these bacilli, as they altogether refused to grow on any of the ordinary culture media and under either aerobic or anaerobic conditions, though this very fact obviously tends to show that they are not of a merely saprophytic nature. In the following year, however, I carried out certain experiments which appear to prove that it is possible to obtain a growth of similar bacilli from variolous material in a particular culture medium and even to carry on such growth in secondary cultivation. The experiments which have been instituted in this direction are but few in number and it is evident that the exact conditions essential to success have yet to be determined. As it seemed to me, the desideratum for the purpose of inducing growth of the supposititious micro-organisms was a medium which had not been artificially sterilised, which *à priori* should afford the necessary pabulum, and which at the same time was secure in its circumstances against contamination. Hence the choice appeared to lie between the intra-peritoneal fluids of one or another living animal and the hen's egg, which has already been made use of as an alternative culture medium. As regards intra-peritoneal fluid I foresaw difficulty in that it is apt to contain leucocytes which might easily vitiate experiment and accordingly I adopted the hen's egg as a matter of first instance. I had no experience to guide me as to the best method of carrying out the inoculation of the egg or as to the period of incubation best suited for the object I had in view, and my attempts for a time therefore met with but small success. My inoculations were carried out by first cleansing the surface of the egg with corrosive sublimate solution and afterwards with alcohol and then breaking a small hole in the shell by means of a sterilised needle and forceps. Through the opening thus made I mixed the yelk and albumen of the egg by means of a platinum needle and then carried out the inoculation by means of a glass capillary pipette, which had recently been drawn out in the blow-pipe flame. For the purpose of such inoculations I employed variolous crusts obtained from the small-pox ships of the Metropolitan Asylums Board. These crusts were rubbed up in a small glass mortar with a minimal quantity of water or sterilised normal saline solution. Of the resulting emulsion a drop or two was then taken up into the glass pipette and the inoculation carried out. Finally, the small hole in the egg was closed up either by means of a small pledget of sterilised cotton-wool soaked in collodion or with melted sealing-wax. The eggs inoculated in this manner were then placed on beds of cotton-wool and kept in the incubator at a temperature of 37° C. Here they were left for varying periods of time, a month being the period which was eventually found to be that which was most desirable. On opening an egg thus treated I found that in its interior was contained a creamy material which in great part had replaced the ordinary egg contents. This material examined in cover-glass specimens appeared to contain a pure culture of one organism only—namely, a bacillus which morphologically was not to be distinguished from the bacillus which I have previously described as to be found in early vaccine lymph.

My next step was to attempt to grow it in subculture and to make observation also of the effect of its direct transference by cutaneous inoculation into the calf. As regards attempts at subculture in all media most usually employed for such purpose, including gelatin, sugar-gelatin, agar, glycerine-agar, sugar-agar, and serum, these at this time failed, as subculture of the bacilli contained in vaccine lymph had always failed when the ordinary culture media are adopted, but with the calf it was different, and as the result of inoculation of egg cultures on this animal I obtained a strain of lymph which after being passed through a series of calves was successfully employed for the vaccination of children. The calves were all subsequently vaccinated with negative results.

More recently Dr. Blaxall and I have been further investigating the possibility of the cultivation in artificial media of the micro-organism specific to small-pox and vaccinia respectively. Our work received considerable impetus by the discovery that certain culture tubes which had been inoculated with vaccine lymph, but which appeared to remain completely sterile, nevertheless contained a growth of a microbe undistinguishable morphologically from that which I found in egg cultures. This growth, although invisible to the naked eye, became obvious when cover-glass impressions were taken from the surface of the nutrient medium and afterwards stained and examined with the microscope. Dr. Blaxall subsequently devised a method by means of which pure cultivations of apparently the same organism were obtained on the surface of agar plates and this not only when vaccine lymph both of human and bovine origin was employed, but from variolous lymph as well. From these plates agar tubes and tubes of peptone beef broth were also in turn inoculated. In these, again, in the first removes practically no growth was visible except on careful examination by reflected light, but as generations further removed from the original stock were obtained the growth became more obvious, showing as a haziness in the fluid media and as a semi-translucent greyish white line on a sloping surface of agar. Broth cultures of the ninth and succeeding generations when employed for the inoculation of calves afforded in our first series of experiments results which we regarded as most encouraging, seeing that we were enabled to carry on the infection to other calves and subsequently to children, in all of which it took the form of apparently typical vaccinia. Some weeks after the calves were vaccinated with active calf lymph but without result. A later series of experiments, however, were not attended with similar success. The reasons for so great a divergence in our results at one and another time are by no means obvious unless possibly the fact of increased vegetative function shown in the latter subcultures of the microbe may have had as a concomitant a lessened degree of pathogenicity. On this point we are at present unable to make any definite statement, but needless to say the investigation is being continued.

Another direction in which our research work has been extended was suggested to us by certain statements in the report of the Berlin Scientific Commission. In that report an account is given of certain experimental inoculations performed by Freyer with the juice of the spleen, liver, inguinal and mesenteric glands, and marrow of previously vaccinated calves. Using such material vesicles were produced by the employment of almost every organ, which shows in Freyer's opinion that the vaccine germ must be conveyed to them by the circulating blood. This general distribution of that micro-organism takes place, he states, up to three or four weeks after vaccination, but no mention is made by him as to the earliest period at which it was found to occur. The greatest amount of success was obtained by the use of inguinal gland and spleen juice. He further stated that since calves were successfully vaccinated with this material the postulate of an absolutely bacteria-free efficacious lymph was complied with. It is of course obvious that where generalised vaccinia occurs as the result of a local vaccination, as, according to Chauveau, is always the case with solipeds, the micro-organism concerned

must have been conveyed to a distance from the original point of insertion by means of the circulation. Presumably this may also take place, although perhaps to a more limited extent, in that form of the disease where, as in the case of the vaccination of the human being or the calf, the resulting disorder remains to all appearance strictly localised, a secondary eruption being prevented by the spleen or other organ, such as the liver, being enabled to seize upon and ultimately destroy any of the specific germs that happen to be carried thither. It seemed to me that if Freyer's results were capable of confirmation the possibility of vaccinating by means of spleen juice, for instance, must depend on the employment of such material at a period sufficiently late to ensure the active principle having reached the particular organ and antecedent to that at which it would have been destroyed. I thought also that if the most favourable period could be determined it would be possible then to obtain a material free from bacterial growth other than that on which its potency for vaccination depended—a material, therefore, which would afford exceptionally favourable opportunity for the isolation of the organism specific to vaccinia. But, unfortunately, notwithstanding the categorical statements in the report of the Berlin Commission, we have been unable as the result of numerous experiments to obtain similar results *quâ* vaccination to those described by Freyer. Neither have we been able to demonstrate the presence of any micro-organism in culture media inoculated from the fresh spleen, liver, or glands obtained at various dates after vaccination or in the interior of fresh or hardened sections of these same organs. We have therefore temporarily abandoned this portion of our inquiry pending the receipt from Freyer of more detailed instructions.

PROTOZOA.

Owing no doubt to the fact that hitherto it has appeared practically impossible to isolate from vaccine or variolous lymph any bacterium which could with reason be regarded as specific to these affections, a number of observers have turned their attention to the search for a micro-organism of somewhat higher type which might by chance be concerned in the dissemination of vaccinia and variola respectively. Among the first experiments in this direction must be mentioned Renault of Lyons in 1881, Van der Loeff in 1886, and Hlava and Pfeiffer in 1887. It was not, however, until the publication in 1892 of Guarnieri's work that interest in the problem was seriously aroused. Since then the literature of the subject has expanded enormously, owing mainly to the labours of numerous continental pathologists, the only English contributions to the mass of experimental work published up to the present being those of Dr. Ruffer and Mr. Plimmer and of Mr. Jackson Clarke. Renault (1881) first called attention to the fact that peculiar bodies which he regarded as parasitic could be demonstrated in the epithelial cells of the vesicles in vaccinia and variola. Van der Loeff also on examining in the warm chamber a hanging drop of clear calf vaccine lymph discovered "numerous small bodies capable of independent movement," of which, however, he gives no further description, although he offered the opinion that they were living organisms which should be classified with the rhizopoda.

In 1887 L. Pfeiffer described the occurrence in lymph obtained from cases of vaccinia and variola of small, unicellular, generally spherical bodies, which he believed to constitute the specific contagium of these diseases. These parasites he found in still greater numbers in the Malpighian layer of the skin, multiplication taking place by division and also by endogenous formation of spores. These statements were in part confirmed immediately afterwards by Rieck. Guarnieri, having invariably found in the epithelial cells of the skin in the vesicular stage of small-pox small particles half as large as the cell nucleus or even smaller, next attempted (in 1892) the cultivation of similar bodies in the living animal. For this purpose he inoculated the cornea of rabbits and guinea pigs with vaccine lymph, with the result that these protozoa, as he considered them, appeared in the cells of the epithelium covering the cornea. After an interval of about fifty hours from the time of inoculation the surface of the cornea was scraped and the material examined in a hanging drop of aqueous humour. Guarnieri also employed for examination sections taken through the site of inoculation and stained in various ways. In either case he found numerous "parasites" within the epithelial cells of the affected area, generally occupying a zone of the protoplasm immediately surrounding the nucleus, but not intruding upon it. In the hanging drop they appeared as little refractile bodies endowed with slight amœboid power. Examination of sections further showed that they vary much in shape and size, and, further, that they are most numerous in the deep layers of the epithelium, the superficial cells not being involved. To this "parasite" Guarnieri gave the name of cytoryctes vaccinæ. Monti obtained similar results and both Guarnieri and Monti exhibited at the International Congress of Medicine at Rome preparations in which they demonstrated the presence of the parasite. Dr. Ruffer and Mr. Plimmer, who in this country had been working at the subject, also attended the Congress and were thus able to compare their own specimens with those shown by Guarnieri and Monti, thereby establishing, according to Dr. Ruffer, the fact that the protozoa described by all of them were identical in character. Dr. Ruffer and Mr. Plimmer, writing in 1894, described the alleged parasite as a small round body which, when treated with appropriate reagents, appears to have a more darkly staining centre. It is, they say, about four times the size of an ordinary staphylococcus and generally lies in a clear vacuole in the protoplasm of the epithelial cells of the stratum Malpighii, and occasionally indents the nucleus, although they have not found it enclosed in the latter body. These observers stated that they have found the same organism in the sections of skin from small-pox patients and in small-pox pustules of the larynx and the trachea. In the same year (1894) L. Pfeiffer not only confirmed the results obtained by Guarnieri but announced also the discovery, in the blood of persons suffering from small-pox and in the blood of children and calves that had been vaccinated, of amœboid cells which he regarded as parasites. These he found to be most numerous during the pyrexial stage of the disorder, whether variola or vaccinia. These bodies, which are somewhat larger in the blood of the calf than in that of the child, being in the latter about a quarter the size of an average blood corpuscle, are, Pfeiffer states, provided with pseudopodia and are occasionally flagellated. According to this observer they also contain from one to four nuclei which are readily stained. These occur free in the blood, not being contained in cells as is the case in the vaccinated cornea; nevertheless, Pfeiffer considers that they represent a similar stage in the life-history of the organism, of which the more mature form is of a cystic nature, to which he gives the name "monocystis epithelialis." This cyst he believes to give rise in due course to a number of spores. It should be mentioned that he describes similar bodies as occurring in various other vesicular eruptions of men and the lower animals. A Japanese observer, Ogata (1895), as the result of careful microscopic examination of stained film-preparations of vaccine lymph derived from the human being and calf and also of human variolous lymph, concludes that certain protozoa which he had been able to demonstrate in each case should be classified with the Gregarinidæ. Further confirmation of Guarnieri's experiments was afforded in 1895 by von Sicherer, Ernst Pfeiffer, and Mr. Jackson Clarke. According to Ernst Pfeiffer the bodies vary considerably both in size and shape, being sometimes as large as a red blood corpuscle. They resemble the corpuscles also in their affinity for certain staining reagents.

There can, of course, be no doubt as to the occurrence of most of the appearances described, although we may not be prepared to accept the interpretation put upon them; and in this connexion it is well to bear in mind not only that the bodies enclosed in cells, described by Guarnieri, Monti, and Ruffer, are said by them to differ essentially in their staining reaction and in their appearance from those of the Pfeiffers, van der Loeff, and others, but also that all the more recent experimental work in this direction has been carried out on the cornea of the rabbit and the guinea-pig, both of them animals which there is reason to believe are insusceptible to vaccinia. It is therefore, I think, conceivable that the "parasites" in question may represent merely the result of epithelial irritation caused by the scarification, together with that—of a non-specific nature, however—set up by the vaccine lymph employed. That such is indeed the case there is now a considerable amount of evidence to show. Thus Ferroni and Massari (1893) expressed the belief that Guarnieri's so-called parasites are in reality derived from the nuclei of the cells or are due to the immigration of leucocytes. They base their opinion on the results of certain

experiments devised by them, in which they inoculated the cornea of rabbits and guinea pigs with croton oil and india ink. On subsequent examination of stained sections they were able to demonstrate the presence in the epithelial cells of numbers of small bodies apparently identical with those described by Guarnieri. It should, however, be stated that Ernst Pfeiffer failed to find them under similar circumstances, although they were invariably present after the inoculation with vaccine lymph. In the annals of the Pasteur Institute for April, 1897, appeared a most important paper by M. Paul Salmon. This investigator brings to bear on the subject a thorough knowledge of modern staining reactions, by the light of which he shows that Guarnieri's parasites, while differing in their affinity for certain stains from either the protoplasm, nucleus, or nucleolus of the epithelial cell, correspond in all respects as judged by such tests to the nuclei of the migratory leucocytes, the chromatin masses of which rapidly break down in the substance of the invaded cells. He sums up the matter in the following words: "Le pseudo-parasite n'est pas une formation endogène; il a donc forcément une origine extra-cellulaire, extra-épithéliale, et *la petite masse de chromatine ne peut avoir qu'une origine; les cellules migratrices.*" The paper is illustrated with drawings showing all stages of the process of invasion of the corneal epithelium by the leucocytes, from that of their first appearance in the underlying tissue to that of their final dissolution, represented by the presence of minute granules of chromatin only, in the protoplasm of the epithelial cells. No one, I think, comparing this plate with the drawings and descriptions of the corneal "parasites" of Guarnieri and others, can fail to be struck with the truth and completeness of Salmon's explanation of the facts previously observed.

Recent researches have tended to confirm the statements of L. Pfeiffer as to the presence also in the blood of variola and vaccinia, especially during the pyrexial stage, of minute, free, granular amœboid cells. It is, however, doubtful whether it is possible to demonstrate a nucleus. These cells, as already mentioned, are regarded by Pfeiffer as the causative agent of these diseases. This question has been investigated in America by Dr. Walter Reed (1897), whose attention was directed in the first instance to the microscopical examination of fresh preparations of the blood of vaccinated monkeys and calves and subsequently to that of vaccinated children and small-pox patients. Of 11 vaccinated animals (9 monkeys and 2 calves) whose blood was examined Dr. Reed found in the blood of 7 (6 monkeys and 1 calf) "granular amœboid bodies, having a diameter about one-third that of a red blood cell" during the active stage of vaccinia, which on the decline of the local inflammation again disappeared. As showing, however, that these bodies have no causative relationship to vaccinia is the fact that Reed occasionally met with quite similar bodies in the normal blood of healthy children and of monkeys. This same observer states that pale amœboid bodies containing a few dark pigment-like granules may also be present in the blood from cases of variola in the human being and the monkey. The blood of vaccinated children and monkeys was found occasionally to contain bodies of like appearance. Dr. Reed does not appear to have known of a paper published in the previous year (1896) by M. F. Müller, an assistant in Nothnagel's clinic in Vienna. Therein Müller gives a description of "small, generally round, colourless granules" which he found constantly present in the freshly drawn blood both of healthy persons and of those suffering from various diseases. These granules—which may, he says, be readily distinguished from blood-plates—would appear to be of like origin with the minute granular amœboid bodies originally discovered by Pfeiffer. Further light has been thrown on this subject by the labours of Stokes and Wegefarth (1897), who carried out a lengthy series of observations in the bacteriological laboratory of the Baltimore Health Department.

The conclusions at which they ultimately arrived may be briefly set out as follows. In the normal blood plasma and serum of man and the lower animals varying numbers of granules apparently derived from neutrophil and eosinophil leucocytes are usually to be found. There is reason to believe that these granules play some part in bringing about agglutination and cessation of mobility of many pathogenic bacteria and of ultimately destroying them, a property possessed by the normal blood. That this is so is judged from the fact that on filtration of dogs' or rabbits' serum through a Müncke porcelain filter this effect on bacteria was no longer exhibited, although the potency of the serum in this direction could be restored by adding to it a sediment containing granules.

Stokes and Wegefarth make also a suggestion which may not impossibly account for the undoubted fact that, as stated both by Pfeiffer and Reed, the minute granular cells described by them are most readily found in the blood during the progress of certain infective diseases, although, as Reed shows, they must also be regarded as normal constituents of the blood. The suggestion referred to is that the bactericidal power of both leucocytes and serum in man and many animals is due to the presence in them of specific granules, derived in either case from leucocytes, which in presence of invading bacteria are given up to surrounding fluids or tissues. As the outcome of the most recent investigations dealing with the question under discussion it must, I think, be admitted that although Guarnieri and others who have described the presence of protozoa in the blood and tissues of man and the lower animals during certain stages of invasion by variola or vaccinia are undoubtedly correct in their statements as to the occurrence of the particular bodies described by them, they are altogether mistaken as to the true nature and affinities of these bodies. There would indeed appear to be good reason for the belief that these so-called parasites are, in fact, nothing more or less than the fragments of amœboid leucocytes which had originally invaded the peripheral circulation and in turn the particular tissue affected under the influence of chemotaxis.

VARIOLA AND VACCINIA IN THE MONKEY.

Professor Michael Foster suggested to me some years ago that in view of possible deterioration of lymph stocks after employment through a long series of generations it would be well if possible to devise some practical means of investigating the efficiency of the protection afforded by some of those at present in use against variolous infection. The inoculation of small-pox on the human subject being now a penal offence I turned my attention to the monkey tribe on account of their similarity in many respects to man, although assured on high authority that they were not susceptible to either vaccinia or variola. On putting the matter to the test, however, I was agreeably surprised to find that this was not the case, the inoculation of vaccine and variolous lymph having each of them given in my hands successful results in every instance in which I have tried it on the monkey. Briefly described, the *modus operandi* has been as follows: the upper arm or occasionally the inner surface of the thigh is shaved on both sides of the body; the skin is then washed with a solution of some disinfectant, such as corrosive sublimate or carbolic acid, and afterwards with alcohol. Each arm (or thigh) is then scarified in three or four places and the lymph well rubbed in. In the first series of experiments I used ether as an anæsthetic, but I afterwards found this quite unnecessary, as the monkey appears by no means to dislike the scratching process, becoming absolutely quiet as soon as the operation is commenced, and remaining with limbs limp and eyes half closed, as if hypnotised, until its termination, when it at once becomes again as lively as ever. In the case alike of variola and of vaccinia the local result of inoculation attains its acme (*quâ* vesiculation) in the monkey, as in the human being, about the eighth day. The first signs of reaction appear usually on the third day, by which time, if variolous lymph has been used, there is a distinct though very thin crust over the site of inoculation. In the case of vaccinia the appearance of crust at this date is less marked. By the fifth day vesiculation in both cases has generally commenced, this becoming more obvious up to the eighth day, though even then it is much less marked in variolous cases than in those which have been vaccinated, the difference being recognised with the greatest ease. Later the vesicle gives place in either instance to a pustule, by which time there is not unfrequently considerable swelling of the skin and subcutaneous tissue and of the nearest lymphatic glands, the pustule gradually dries up and a scab is formed, which is more pronounced in the case of vaccination than variolation, and which falls off some time during the third week, if the monkey has not picked it off before. The chief difference noticed between the effects resulting from the local inoculation of these two diseases is that in the case of variola there is more or less of a crust from the first; that vesiculation is less marked than

n vaccination; that about from the ninth to the eleventh day a general eruption may appear which in some instances, as in a monkey which, at the request of Professor Foster, was inoculated at Cambridge, covers the whole surface of the body; and that the final scab at the site of inoculation is not so elevated in the variolated as in the vaccinated animal. In both cases there is usually a rise in body temperature, which is more marked and longer sustained in variola than in vaccinia. After variolation it was noticed in several cases that the monkey suffered from diarrhœa, that its eyes were suffused, and that it was not as active as usual. A peculiar odour was also noticed quite distinct from the well-known smell of "monkey." In no instance had the experiment a fatal termination.

Having thus proved to my own satisfaction that monkeys are susceptible not only to vaccination but also to small-pox I next determined to make trial as to the protection against small-pox afforded in the monkey by previous vaccination and the protection against vaccination afforded it by variolation, and I went on to compare the effect produced by the use of human and of calf vaccine respectively. For this purpose humanised lymph was obtained from Birmingham, where, to the best of my belief, the same strain has been continuously carried on by means of arm-to-arm vaccination for the past 38 years. The calf lymph used was obtained from the Government Animal Vaccination station in Lamb's Conduit-street, while small-pox lymph was supplied to me from the hospital ships, from Warrington, and from Manchester. The following experiments will serve as illustration of the system I pursued:—

Experiment 1.—On July 13th, 1892, I vaccinated a male rhæsus monkey in four places on the left arm with calf lymph on points taken at the Animal Vaccine Establishment on the previous day. On July 20th, the eighth day, the appearance presented was undistinguishable from that of a successful case of human vaccination. On July 23rd the vesicles had given place to four large scabs raised nearly ⅛ in. above the surface of the arm, while the surrounding inflammatory zone had nearly disappeared; the axillary glands on the same side were considerably enlarged. The arm was drawn on this day by Mr. Lapidge. By Aug. 9th the scabs had all come off and the monkey was again vaccinated, but this time on the opposite arm in two places and on the inside of the right thigh, also in two places, with humanised lymph of ascertained activity. The animal was carefully examined day by day up to Aug. 17th, but no sign of the second vaccination having "taken" was observed.

Experiment 2.—On July 19th a large female rhæsus monkey was inoculated by scarification in eight places (four on each arm) with two tubes of small-pox lymph from the hospital ships. It was obtained from a patient, aged nineteen years, stated to have been vaccinated in infancy, who was suffering from a semi-confluent attack of the disease. The lymph had been sealed up in carefully sterilised tubes. On July 23rd (the fifth day) the right arm showed papulation and commencing vesiculation. The axillary glands were slightly enlarged. On April 18th, a month after inoculation, this monkey was vaccinated in four places on the inner aspect of the right thigh with active calf lymph. No result followed the operation.

It is, I think, hardly necessary here to enter into details of the numerous experiments which have been performed at intervals of from one to five months after the primary inoculation, whether vaccinal or variolous, and I will merely add that in no instance did anything in the nature of a successful result follow the first or subsequent revaccinations. From these experiments it would appear that the protective power of lymph obtained from these three different sources when inoculated on the monkey is practically identical in all respects.

In discussing the origin of the various lymph stocks at present in use Dr. Collins and Mr. Picton in the Minority Report appended to the Final Report of the Royal Commission on Vaccination make a point of the impossibility of employing at the present day what used to be known as the "variolous test" as a proof of the efficacy or the reverse of any particular strain of lymph. In view, however, of the results of my experiments with monkeys this criticism of Dr. Collins and Mr. Picton falls to the ground, since if it is desired to apply the "variolous test" to any given lymph stock all that is necessary is to vaccinate a monkey with a sample of the lymph in question and subsequently to inoculate the animal with potent small-pox lymphs after the lapse of such period from the first operation as may be thought desirable.

ABSTRACT OF TABLES ILLUSTRATING

The Hunterian Lectures.

BY HENRY MORRIS, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL.

THE Hunterian Lectures, abstracts of which were published in THE LANCET of April 16th, 23rd, and 30th, were illustrated by a valuable series of tables of cases of operations on the kidney. All the tables except the last refer to cases operated on by Mr. Morris. Table I. recording the cases of nephrolithotomy performed by Mr. Morris himself we print herewith, but we regret that the demands on our space prevent us from giving more than a *résumé* of the others.

Table II. contained cases of nephrotomy for stone. There were 44 cases in all and of these 27 occurred in males and 17 in females. The youngest patient was a male, seventeen years old, and the oldest was also a male, aged sixty-four years. The results were as follows: 33 cases recovered from the operation, one of these dying seventeen days later from apoplexy, and in 11 cases the patient died within a short time of the operation though the fatal result was in several of the cases hardly to be attributed to the operation itself.

Table III. contains Mr. Morris's cases of nephrectomy for stone. These are 18 in number, with 5 deaths. 13 of the cases were males and 5 were females.

Table IV. Exploratory Operations.—These cases show clearly the great value of an exploration when the symptoms point to some morbid renal condition; in many of the cases Mr. Morris was able to remove the cause of the symptoms, even though no stone was found. There were 42 exploratory operations and only 2 of the patients died, and of the remainder all were relieved with the exception of 7.

Table V. Operations for Moveable Kidney—In 57 cases Mr. Morris has fixed a moveable kidney and all have recovered, though in one instance the patient was not relieved by the operation.

Table VI. Operations for Hydronephrosis and Pyonephrosis.—In 20 cases there were only 3 deaths.

Table VII. Operations for Tuberculous Disease of the Kidneys.—Of 28 cases 20 occurred in females. In some cases nephrotomy, in others nephrectomy, and in a few partial resection were performed. 5 cases died soon after the operation, but 4 others died later from tuberculosis elsewhere.

Table VIII. Nephrectomy for Fistula or other Cases.—Of 5 cases 3 recovered and 2 died.

Table IX. Operations for Tumours of the Kidney.—There are in all 15 cases—1 of retro-peritoneal tumour connected with kidney, 5 of cystic disease of the kidneys, and 9 of malignant disease of the kidneys. One of the cases with cystic disease died and 3 of the malignant cases; 2 others of the latter died later from recurrence.

Table X. Operations for Injury of the Kidney.—There were 4 cases and all recovered; in 2 the kidney was explored, in 1 nephrectomy was performed, and in 1 ureterectomy.

Table XI. Collected Cases of Calculous Anuria.—In 33 cases an operation has been performed for this condition. The earliest was by Guermonprez in 1870. Of the 33 cases 25 died. This mortality must be considered in relation to the very fatal result of the disease when left untreated.

TABLE I.—CASES OF NEPHROLITHOTOMY.

Year.	No.	Sex.	Age.	Leading symptoms.	Date of operation.	Result.	Remarks.
1880	1	Female.	19	Excessive pain and tenderness in right loin. Great hæmaturia, quite disabling her from work. Symptoms acute for 17 months. Occasional pain in right side for 11 years.	Feb. 11th, 1880; right kidney.	Recovered.	Incision into anterior surface of kidney near hilum. Recovered with a sinus from 1 in. to 1½ in. long, not communicating with the kidney. Weight of calculus, 31 gr. (Vide Transactions of the Clinical Society, vol. xiv., 1881.)
1884	2	Male.	24	Shooting pains to left testis and tenderness in left loin. Some hæmaturia. Frequency of micturition. Symptoms for 2 years	May 10th, 1884; left kidney.	Recovered.	Incision into anterior and lower part of kidney. No sinus. Weight of calculus, 89½ gr. (Vide Transactions of the Clinical Society, vol. xviii.)
1886	3	Male.	42	Pain in right loin. Hæmaturia. Symptoms for 19 years.	May 15th, 1886; right kidney.	Recovered.	No sinus. Weight of calculus, 23½ gr. (Vide Transactions of the Clinical Society, vol. xx.)
1887 (P)	4	Male.	25	Tenderness and aching in left loin. Hæmaturia and slight pyuria. Never colic. Kidney felt hard. Symptoms 9 years; worse of late.	March 16th, 1887; left kidney.	Recovered.	Calculus removed from pelvis. Weight of calculus, 213 gr. No sinus. Nephrotomy and nephrectomy ten years after for recurrent calculus.
1888 (P)	5	Female.	26	Pain in both loins, but chiefly in right, for 4 years. Hæmaturia. Slight pyuria. Oxalate of lime crystals. Tenderness in right loin. Frequency of micturition for 1 year.	Jan. 18th, 1888; right kidney.	Recovered.	Incision into anterior aspect of kidney. No sinus. Weight of calculus, 199 gr.
1889	6	Female.	21	Pain in right loin for 4 years. Swelling for 1 week, which was freely moveable. Hæmaturia and albuminuria.	May 22nd, 1889; right kidney.	Recovered.	One large stone and 7 fragments removed. Total weight of calculus, 1303 gr. Urinary sinus followed. Subsequent left nephrolithotomy, 1890, and right nephrectomy 1891. (Vide No. 9.)
1889	7	Male.	27	Pain and passage of calculi. Slight pyuria. Repeated attacks of pain for 8 years.	July 31st, 1889; right kidney.	Recovered.	Three calculi removed from kidney. Weight of calculi, 69 gr. No sinus.
1890	8	Male.	23	Pain on right side. Hæmaturia. Passed blood in urine when a child and had had pain for 10 years.	Feb. 23rd, 1890; right kidney.	Recovered.	Incision into anterior aspect. Three branched calculi were removed from the renal substance and a much larger one from the pelvis. Total weight 200 gr. Recovered without a sinus.
1890	9	Female.	22	Pain in left loin very severe.	April 23rd, 1890; left kidney.	Recovered.	Incision into pelvis of kidney. Weight of calculus, 513 gr. Sinus present but not urinary sinus. (For previous nephrolithotomy *vide* No. 6.)
1890	10	Male.	40	Pain and tenderness in left loin for more than 20 years.	June 7th, 1890; left kidney.	Recovered.	An oxalate of lime calculus was removed from the cortical part of the kidney. Weight of calculus, 62 gr. No sinus remained.
1890	11	Male.	34	Pain in left loin for 2 years. Hæmaturia, pyuria, and oxalate of lime crystals.	Aug. 29th, 1890; left kidney.	Recovered.	Incision into anterior aspect, and stone found lying in the kidney substance close to the pelvis. Weight, 129 gr. No sinus remained.
1891	12	Male.	35	Pain and swelling in right loin for 1 year. Hæmaturia and pyuria.	Feb. 11th, 1891; right kidney.	Recovered.	Incision into anterior aspect and extraction of a stone. No sinus. Weight of calculus, 27½ gr.
1891	13	Male.	26	Pain and tenderness in left loin and hæmaturia for 2 years.	April 29th, 1891; left kidney.	Recovered.	Incision into anterior surface near hilum. No sinus. Weight of calculus, 38 gr.
1891	14	Male.	48	Pain in left loin for 6 years and hæmaturia on three occasions 3 or 4 years ago, but not since. Frequent severe colic during last four months. Pain shooting into left groin.	May 9th, 1891; left kidney.	Died May 13th, with symptoms of uræmia and intense mental agitation.	The patient was a very stout man and the kidney was very difficult to reach through an oblique wound 12 in. long joined by a vertical incision 3 in. long. Brisk hæmorrhage followed renal incision, but was soon stopped by pressure. Two stones were removed. Post-mortem wound in left kidney 1½ in. long. Left kidney weighed 7½ oz. and was fatty. Right kidney weighed 5½ oz. and was fatty, as were also the liver and the heart. Small branch of renal vein divided and plugged by recent clot. No injury to peritoneum. Weight of calculi, 19½ gr.
1892	15	Male.	35	Pain in left loin, radiating to scrotum. Hæmaturia. Frequent micturition. Symptoms 1 year.	Jan. 3rd, 1892; left kidney.	Recovered.	Incision into convex border of kidney. No sinus. Weight of calculus, 18 gr.
1892 (P)	16	Female.	35	Attacks of pain and frequent micturition. Hæmaturia for 7 years. Pain in right side and occasionally in left.	July 13th, 1892; right kidney.	Recovered.	Calculus weighed 362 gr. No sinus.
1892 (P)	17	Female.	25	Pain for two months and suppression of urine from left kidney. In November, 1891, a calculus was removed from the right (pyonephrotic) kidney by another surgeon. A large abscess followed and this was succeeded by a sinus. The urine from right kidney was discharged through the loin by the old nephrotomy sinus.	Dec. 24th, 1892; left kidney.	Recovered.	Left kidney drawn on to loin and incised in three places. Twenty-two phosphatic calculi were removed. Weight of calculi, 96 gr. An abscess followed; but on Jan. 9th wound closed and was never afterwards reopened. All attempts to close sinus on the right side were followed by severe symptoms requiring sinus to be reopened. A canula was therefore at length permanently maintained on the right side.

[*Table I. continued on next page.*

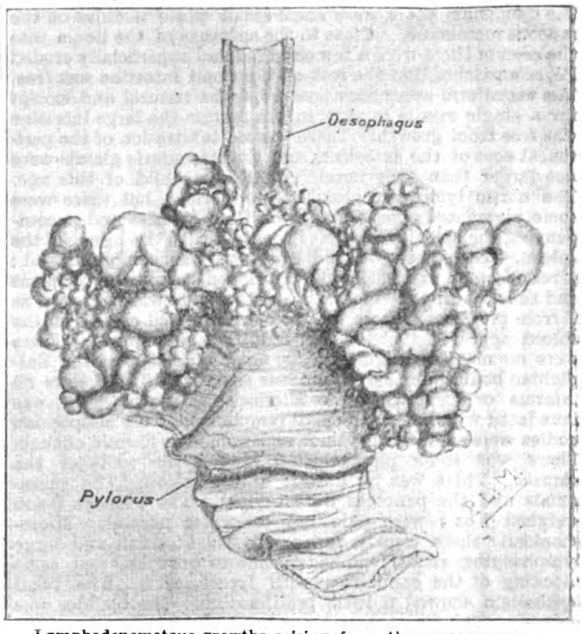
TABLE I.—CASES OF NEPHROLITHOTOMY *(continued)*.

Year.	No.	Sex.	Age.	Leading symptoms.	Date of operation.	Result.	Remarks.
1893 (P)	18	Male.	13	Pain in right side for 7 years. Albuminuria and occasional hæmaturia.	May 13th, 1893; right kidney.	Recovered.	Tuberculated heart-shaped stone removed from pelvis of kidney. Weight 33 gr. No sinus.
1893 (P)	19	Female.	35	Pain and tenderness in right renal region for 4 or 5 months. Pain on micturition, necessitating a vesico-vaginal fistula for 10 years.	May 14th, 1893; right kidney.	Recovered.	A small lozenge-shaped uric-acid calculus removed. No sinus. After operation all painful micturition disappeared and vesico-vaginal fistula was closed by operation. Weight of calculus, 4 gr.
1893 (P)	20	Male.	38	Had been operated upon in February, 1893, for a perinephric abscess on left side. This re-formed and was opened on June 10th, 1893. A sinus followed. In November, 1892, and at both the above-named dates there was marked anuria.	June 29th, 1893; left kidney.	Recovered.	Three calculi removed. The kidney was small and somewhat hydronephrotic. In this case an abdominal incision was made as well as the lumbar. Only a few ounces of urine passed by urethra till operation wound began to close. On July 11th 11 oz. were voided naturally and from this time the quantity gradually increased. Weight of calculi, 17 gr. No sinus remained.
1893	21	Male.	21	Pain in right loin for 1 year. Hæmaturia, albuminuria, and pyuria.	Sept. 27th, 1893; right kidney.	Recovered.	Incision made into the organ and a stone extracted. Weight of calculus, 40 gr. No sinus remained.
1894 (P)	22	Female.	35	Lumbar pain on left side. Pyuria with very high temperature and nervous agitation. Hard irregular swelling in right loin, to which no symptoms had been referred and which was not known by patient to exist.	May 17th, 1894 (1st operation); right kidney.	Recovered.	A large calculus removed, weighing 830 gr., which was closely enveloped by the dilated pelvis and upper end of ureter. Urinary sinus persisted. Subsequently nephrotomy was performed on both kidneys.
1894 (P)	23	Male.	49	Previous passage of many calculi—the first 20 years ago, the last in January, 1894. Pain in left loin. Pyuria and hæmaturia and also ova of bilharzia hæmatobia.	May 29th, 1894; left kidney.	Recovered.	An incision in the loin 9 in. long joined by a vertical incision 1½ in. long. Incision into convex border of kidney and a uric-acid calculus, weighing 35½ gr., extracted from the lower fourth. No sinus.
1894	24	Female.	22	Pain and resistance in right loin for 1 year. Albuminuria, pyuria, and hæmaturia. Oxalic and uric acid crystals.	Aug 20th, 1894; right kidney.	Recovered.	Incision into convex border and a calculus extracted weighing 5 gr. Incision in kidney closed with catgut sutures. No sinus.
1895	25	Male.	30	Pain in right loin for 4 years. Hæmaturia and albuminuria. Oxalate of lime crystals.	Jan. 2nd, 1895; right kidney.	Recovered.	Incision into pelvis and ureter. Stone impacted at entrance of ureter; removed through incision in renal pelvis. No sutures. No sinus. Weight of calculus, 6 gr.
1895	26	Male.	11	Pain in right loin. Hæmaturia and pyuria. Duration of symptoms 3 years.	Oct. 11th, 1895; right kidney.	Recovered.	Incision into pelvis of kidney, which was closed by silk sutures. Stone size of small plum-stone extracted. No sinus. Weight of calculus, 8 gr.
1896	27	Male.	20	Pain in left loin for 4 years. Occasional hæmaturia.	March 3rd, 1896; left kidney.	Recovered.	Incision into pelvis of kidney. Stone size of hazel nut extracted. No sinus. Weight of calculus, 25 gr.
1896 (P)	28	Female.	18	Pain in left loin. Hæmaturia. Symptoms since twelfth year of age.	March 15th, 1896; left kidney.	Recovered.	Calculus removed through the front of the renal pelvis. The incision was sutured. No sinus. Weight of calculus, 25 gr.
1896 (P)	29	Male.	58	Pain in left loin. Hæmaturia. Periodic attacks every 6 months for 8 years. During last 2 years attacks much more frequent. For several weeks preceding operation hæmaturia constant.	Aug. 1st, 1896; left kidney.	Recovered.	Incision into posterior aspect of renal pelvis. Oxalate of lime calculus removed weighing 41 gr. No sutures were used for the pelvis. No sinus.
1897	30	Male.	48	Pain in right loin for 40 years. Albuminuria, pyuria, and oxalate crystals.	July 28th, 1897; right kidney.	Recovered.	Incision into the anterior aspect of kidney and a stone removed from its lower part. No sinus. Weight of calculus, 147 gr.
1897	31	Female.	29	Pain in left loin for 16 years.	July 28th, 1897; left kidney.	Recovered.	Incision into pelvis and a stone extracted. The renal wound was sutured with 4 fine catgut sutures. No sinus. Weight of calculus, 35 gr.
1897	32	Female.	22	Pain and swelling in right loin for 6 months. Hæmaturia, pyuria, and albuminuria.	Nov. 22nd, 1897; right kidney.	Recovered.	Incision into posterior wall of pelvis and a friable, irregularly shaped stone was removed. Wound in pelvis was sutured. No sinus. Weight of calculus, 2 gr.
1897 (P)	33	Male.	44	Repeated attacks of pain and tenderness on left side for 16 years. Occasional hæmaturia. An abiding aching aggravated by exercise. No pus; no crystals in urine.	Dec. 18th, 1897; left kidney.	Recovered.	Calculus removed from upper end of ureter by an incision through posterior surface of pelvis. No sutures used, as the tissue of renal pelvis was very soft. No sinus remained. Weight of calculus, 17 gr.
1898	34	Female.	26	Pains in left loin for 2 years. Repeated attacks of left renal colic, accompanied by temporary complete suppression of urine, which lasted for 2 or 3 days at a time. There was enlargement of right kidney, which was also believed to contain a stone, but to which no symptoms were referred. During attacks of pain a swelling was felt in left renal region.	Jan. 26th, 1898; left kidney.	Recovered.	Kidney large and congested. An incision was made in the convex border and through it a stone weighing 11 gr. was extracted from the renal pelvis. Uninterrupted recovery. No sinus. To return for purpose of having right kidney explored.

A CASE OF LYMPHADENOMA INVOLVING THE STOMACH IN A CHILD AGED EIGHTEEN MONTHS COMPLICATED BY RICKETS AND CLOSELY SIMULATING LEUKÆMIA.

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE VICTORIA HOSPITAL FOR CHILDREN;

AND



A. C. LATHAM, M.B. OXON., M.R.C.P. LOND.,
CURATOR OF THE MUSEUM, ST. GEORGE'S HOSPITAL; ASSISTANT PHYSICIAN TO THE VICTORIA HOSPITAL FOR CHILDREN; LATE RADCLIFFE TRAVELLING FELLOW IN THE UNIVERSITY OF OXFORD.

THE patient, a male infant, aged one and a half years, was admitted to St. George's Hospital on Feb. 14th, 1898, and died two days later. He was under the care of Dr. Cavafy, who has kindly allowed us to make use of the case. Two months previously the child had been operated upon for a (granulation?) polypus in the right ear and since then had been losing strength and colour. The mother said that the child had brought up blood. A week before admission spots were noticed on the skin which at the post-mortem examination were seen as scattered petechiæ. There was a tender swelling behind the right parotid, and the spleen was found to be much enlarged, but no abnormal signs were discovered in the lungs. The child was very anæmic, but did not complain or appear to suffer any pain except when the right side of his neck was examined, and died quietly from increasing asthenia two days after coming into the hospital.

Owing to the fact that we did not see the patient during life we were unable to make a complete examination of the blood—for instance, we have no data with regard to the absolute number of white and red cells. We were fortunate, however, in having several blood films prepared by Mr. S. Smith, the house physician of the case. An examination of these films showed that there was very considerable degeneration of the red cells and that this was accompanied by a large increase in the number of white cells. A differential count of 500 white cells gave the following figures: lymphocytes, 61·1 per cent.; polynuclear cells, 16·5 per cent.; eosinophile cells, 1·6 per cent.; and myelocytes, 20·8 per cent. During this count 94 normoblasts and 6 megaloblasts were noticed; many of these showed mitotic changes. There were no Charcot-Leyden crystals. The blood thus showed very marked anæmia, together with a marked increase in the number of lymphocytes—many of which were of the larger form—and a very large percentage of cells foreign to normal blood—namely, myelocytes.

At the necropsy the body was found to be markedly anæmic with scattered but not very numerous petechiæ. There was slight œdema of the legs. There were marked rickety curves of the tibiæ and enlargement of the wrists. There was a hard swelling in front of the sterno-mastoid muscle on the right side reaching up into the parotid region. On dissection this was found to be a packet of glands passing underneath the sterno-mastoid muscle. The glands appeared gelatinous from œdema and the fibrous tissue separating them seemed prominent and increased in amount. Microscopically, the packet of glands on the right side of the neck showed thickening and increase of their fibrous capsules; the normal arrangement of the glands was obscured and lost. There was a general slight increase of the fibrous tissue throughout the tissue of the gland with a number of oval connective tissue cells. The number of small lymphocytes was diminished but large lymphocytes were present in considerable quantities. These cells appeared to be the same as those described by many writers as endothelioid cells. The other accessible lymphatic glands in the body were examined but were not found to be enlarged. The anterior fontanelle was open, but not widely; the diploe and bones of the skull-cap were healthy. The membranes and sinuses were normal. The brain weighed 36 oz. and was healthy. Both membranæ tympana were perforated and the middle ears contained soft granulation tissue polypi and muco-pus. The sternum appeared to be normal on section. The ribs showed very marked rickety enlargement at their costo-chondral junctions, there being in several instances some backward displacement of the rib on the costal cartilage. At a distance of from 1½ in. to 2 in. from the costo-chondral junction several of the ribs showed periosteal nodes which on section invaded the medullary cavity and rather suggested a united fracture. But as the node was only on one side, the fracture, if there had been one, must have been a "greenstick." The rickety enlargement was very vascular and was in places excavated into loculi; reddish marrow extended some distance into the shafts of the ribs, in some as far as the periosteal nodes already referred to. There was no hæmorrhage under the periosteum or sign of scurvy rickets. Microscopically, besides marked evidence of rickets, the costo-chondral junction showed an excess of lymphocytic infiltration as compared with normal bones from a child of the same age. This lymphocytic infiltration was also present in the shafts of the ribs: this condition might be thought to resemble, but only in a very minor degree, the lymphadenomatosis of bone described by Weber.[1] The nodes on the ribs were composed of ossifying cartilage; under the node there was a transverse break on the underlying lamina of bone strongly suggesting that a partial fracture had occurred some time before death. The bones of the limbs were not examined. The thymus and thyroid glands were healthy. The pleuræ were normal. The lungs showed early broncho-pneumonia with small hæmorrhages into their substance. The bronchial and tracheal glands were healthy. There were petechiæ on the visceral pericardium. The cardiac valves were healthy. The myocardium was pale but there was no manifest fatty degeneration. The abdomen was distended from the presence of flatus in the intestines; but there was no ascites. The œsophagus was perfectly normal. The outside of the stomach near the lesser curvature showed a few plaques of white growth. The stomach contained some grumous fluid. Its mucous membrane presented a remarkable appearance (vide Fig. 1) from the presence of a number

FIG. 1.

Lymphadenomatous growths arising from the mucous membrane of the stomach. The only part not affected is the region around the pylorus.

of polypoid growths that were scattered all over the lining mucous membrane except for a distance of from 1 in. to 1½ in. around the pylorus. The growths were smooth, white, and not ulcerated. These were of varying size, the largest being equivalent to a small walnut. They were largest and most

[1] F. P. Weber: General Lymphadenomatosis of Bone, one form of Multiple Myeloma. Journal of Pathology and Bacteriology, January, 1898.

closely packed near the cardiac orifice, gradually diminishing as the pyloric region was approached. Microscopically the polypoid growths were composed of the mucous membrane thrown into folds and extensively infiltrated with large and small lymphocytes (vide Fig. 2). The submucous coat did not

FIG. 2.

Microphotograph of lymphadenoma of the stomach × 12 showing infiltration limited to the gastric mucosa and not invading submucosa.

contain any lymphocytes at all. This growth, which also contained some spindle-shaped connective tissue, was apparently derived by proliferation of the lymphoid tissue that is normally found on the mucosa. The tubular glands of the stomach were somewhat displaced by the growth but showed no proliferation or degeneration and were well preserved. The duodenum showed some vascular streaks from which the stomach was quite free. In the second and third parts of the duodenum there were some small white nodules on the mucous membrane. Close to the entrance of the ileum into the cæcum there were a few enlarged and superficially eroded Peyer's patches, but the rest of the small intestine was free. The vermiform appendix appeared to be natural and except for a single sessile growth in the rectum the large intestine was free from growth. There was no infiltration of the peritoneal coat of the intestines and the mesenteric glands were not larger than they normally are in a child of this age. The aortic lymphatic glands were normal, but there were some pigmented glands along the iliac arteries and accompanying the splenic artery at its entrance to the hilum of the spleen. The spleen weighed 8 oz. and was much enlarged; it rested on an extremely well-developed costo-colic ligament and the adjacent splenic flexure of the colon was collapsed as if from pressure. There was no capsulitis and on section the spleen appeared to be tough, reddish, and uniform. There were no manifest pigmentation, no enlargement of the Malpighian bodies, and no lardaceous reaction. There were no infarcts or hæmorrhages. Microscopically the pulp was inundated with large and small lymphocytes; the Malpighian bodies were small but had not undergone any fibrotic change. There was some pigmentation around the walls of the sinuses. There was no fibrosis of the spleen. The suprarenals and the pancreas were normal. The kidneys (each weighed 1 oz.) were pale but otherwise normal. Microscopically there were a few small foci of small and large lymphocytes, small lymphadenomatous growths, and some blocking of the capillaries with lymphocytes. The tubal epithelium showed a little proliferation. The bladder was normal. The testes were large but healthy. The liver was enlarged to a slight extent and on section appeared to be swollen and pale. There was a large white gland in the portal fissure, but there were no growths on the substance of the organ. The bile-ducts were pervious. The gall-bladder was almost empty. Microscopically there was a general excess of lymphocytes in the capillaries, so that the liver appeared to be in a state of early leukæmia. In addition there was in the portal spaces and outside the capillary vessels early lymphadenomatous growth composed of lymphocytes and young connective tissue-cells. There was no cirrhosis or fatty change.

Remarks.—Viewing the case in the first place from the standpoint of the blood examination alone the case would plainly have to be described as one of lieno-myelogenous leukæmia. The small percentage of eosinophile cells is unusual, but the majority of observers are agreed that the part played by eosinophile cells in leukæmia is unimportant. Some of the blood changes are undoubtedly due to the fact that the child was suffering from marked rickets. In this disease there is considerable anæmia, which is often accompanied by a lymphocytosis and a small (from 2 to 3 or less) percentage of myelocytes. In this patient, however, the large percentage of myelocytes was far in excess of anything that has been found in any other disease than leukæmia. Again, a part of the lymphocytosis and the small number of polynuclear cells might readily be accounted for by the age of the child, so that it is fair to regard the excess of small lymphocytes as due to some other cause than leukæmia. In fact, our knowledge of the changes which occur in the blood in children is not sufficiently accurate for us to form any definite conclusions on a blood examination alone in such a case as this. It might be suggested that the case should be classified under what von Jaksch[2] and others have called "anæmia infantum pseudoleukæmica." It is very doubtful, however, whether this name can be fairly given to any class of disease. The vast majority of cases recorded under this heading have not been examined in a sufficiently thorough manner in the matter of a differential count of the white cells for us to say under what classification they should be put. Further, very different types are given by different observers. We agree with von Limbeck[3] that no such disease exists and we believe that Cabot[4] is right in suggesting that the cases which have been recorded as cases of "anæmia infantum pseudoleukæmica" are in reality either cases of pernicious anæmia, secondary anæmia without leucocytosis, Hodgkin's disease, lymphatic leukæmia, or possibly cases of spleno-myelogenous leukæmia. It is further possible, as Cabot suggests, that there may be cases which are intermediate between leukæmia and pernicious anæmia. Turning to the point of view of the morbid anatomy the case appears to be a remarkable example of lymphadenoma. The growth, as is so often the case, apparently began in the cervical glands, and it is probable that the poison, whatever it may be, which gives rise to lymphadenoma gained entrance to the lymphatic system through the abraded surface in the right tympanum. Starting here, the growth had become general and, a noteworthy feature in the case, chiefly in the alimentary canal and especially in the stomach. The spleen was much enlarged and there was some infiltration of the ribs. These latter lesions, as will be seen, are of great interest. Now though lymphadenoma, unlike leukæmia, is far from rare in young children, it appears that lymphadenomatous growths from the gastric mucous membrane have not been previously described at so young an age. The youngest case which Pitt[5] recorded was twenty-four years old and the average of his 5 cases was 44·8 years. The morbid appearances in our case closely resemble those in Pitt's own patient, who was forty-eight years old. In both the mucous membrane of the stomach around the pylorus, in the antrum pylori, was free from lymphadenomatous growths. This is very striking, especially in Pitt's case, when it is considered in the light of the anatomical distribution of lymphoid tissue in the mucous membrane of the stomach. From a number of observations Soltau Fenwick[6] concluded that in "infancy and childhood these collections of lymphoid tissue are fairly developed and profusely scattered over the whole surface of the organ, but are always particularly large and distinct in the pyloric region near the lesser curvature. After the age of forty it is often impossible to demonstrate their presence in the cardiac two-thirds of the stomach without the use of the microscope, and in the pyloric region they are much reduced in numbers and appear small and shrunken." The growths have therefore in both cases avoided the parts where the lymphoid follicles are normally best developed, and in Pitt's case were present where the lymphoid tissue is usually atrophied at that age. It is plain, then, that although the disease appears from the morbid anatomy

standpoint to be lymphadenoma, yet it presents some unusual features in such points as the distribution of the disease. So far we find that the blood examination points to a diagnosis of lieno-myelogenous leukæmia and that post-mortem evidence gives support to the diagnosis of lymphadenoma. If the disease were leukæmia throughout there ought to have been much more marked leukæmic infiltration of the liver and the kidneys than was present, for it is probable that if the large polypoid growths in the stomach were due to lymphocytic infiltration occurring in lymphatic leukæmia the other organs should be affected to a corresponding degree. On the other hand, the examination of the sections of the liver and kidney showed that the capillaries were in places filled with lymphocytes, thus supporting the diagnosis of early leukæmia. Against leukæmia, however, we have to face the fact that only two cases of genuine leukæmia in infancy have been recorded,[7] and that of these only one was of the lieno-myelogenous type. In this case there was a percentage of 21 myelocytes and this was associated with a large increase in the number of white cells and an abundance of nucleated red cells. It is possible to regard the case as primarily one of Hodgkin's disease which in its later stages had taken on the characteristics of leukæmia. There is no doubt that cases which clinically are primarily cases of Hodgkin's disease do before death develop the blood characteristics of leukæmia. It may be that towards the end of a case of lymphadenoma we get in some instances what may be called a lymphadenoma of the blood—that is to say, the process in the glands becomes acute and there is secondary invasion into the blood, getting in this way the appearance of lymphatic leukæmia, just as in sarcoma a secondary invasion occurs by means of the blood. This secondary invasion in sarcoma is, it may be noted in passing, often associated with what appears to be a lymphocytosis. This occurrence thus becomes very interesting, not only from the point of view of the relationship between lymphadenoma and leukæmia, in which the lymphatic glands and the leucocytes are respectively affected, but as bearing on the relationship of lymphadenoma to sarcomatous growth. The close connexion of these diseases is made more evident by the result of Muir's[8] careful study of a series of leukæmic cases; he comes to the conclusion that the changes in both forms of leukæmia are due to the proliferation of a certain cell—possibly owing to the action of some irritant—in a manner analogous to what is found in certain tumours, such as sarcomata. In this particular case the morbid appearances suggest Hodgkin's disease, the blood examination points to a mixed leukæmia, and in view of the above it might be held that the case was primarily Hodgkin's disease and secondarily had taken on the blood characteristics of lieno-myelogenous leukæmia. Against this, however, we know in the first place that strange variations occur in the blood of children without any very apparent cause, and further although the blood examination is in itself very much in favour of lieno-myelogenous leukæmia, yet considering the age of the child it does not justify the conclusion that the case was leukæmia. This conclusion is very much strengthened by the fact that there appears to be no record of any case of lymphadenoma which went on to lieno-myelogenous leukæmia, although cases of Hodgkin's disease indistinguishable in the late stages from cases of lymphatic leukæmia are common. It would seem best to regard the case as one of aberrant lymphadenoma in which changes simulating lieno-myelogenous leukæmia had been induced by a marked condition of rickets. As has already been pointed out, the large amount of lymphocytosis and the marked anæmia with the presence of nucleated red cells is what is found in rickets. Further, in rickets there is apparently no increase in the number of eosinophile cells and this would be in keeping with the small number—practically normal—of eosinophile cells present in this particular case. Again, the age of the child might account for the relatively small number of polynuclear cells present. So far then we have accounted for all the blood changes with the exception of the presence of the abnormal cells or myelocytes. A very small percentage of these cells is common in rickets. It is probable that the infiltration of the marrow of the ribs by lymphadenomatous material which occurred in this case may have acted in some way in conjunction with the marked rickety condition, either as an irritant or otherwise, so that it caused a more or less intense proliferation of the cells which are found in bone marrow but are foreign to the blood—namely, the myelocytes. Viewed in this light it seems best from post-mortem evidence to regard the case as one of lymphadenoma complicated by rickets, especially as the blood changes can be satisfactorily explained by this combination of diseases.

For the drawing of the stomach and the micro-photograph we are indebted to Mr. P. L. Mummery, B.A., and Mr. Harold Spitta, senior students at St. George's Hospital.

A METHOD OF EXPOSING AND OPERATING ON THE KIDNEY WITHOUT DIVISION OF MUSCLES, VESSELS, OR NERVES.[1]

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,
SENIOR SURGEON TO THE GENERAL INFIRMARY AT LEEDS AND PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE.

MY much lamented friend, the late Greig Smith, used to insist on the importance of opening the abdomen in the course of the muscular fibres as much as possible so as to avoid the weakness that is apt to follow on division of muscle, but I can find no evidence in his writings, nor did I gather in my many conversations with him, that he had conceived the idea of exploring the kidney on this principle. Dr. McBurney's method of exposing the vermiform appendix, which I have employed on numerous occasions with great satisfaction, suggested to my mind the possibility of exposing the kidney in a similar manner, and it was not until I had performed a number of operations by the method I am about to describe that my attention was drawn to a paper by Dr. Abbé in the Transactions of the New York Surgical Society, in which he describes a case of nephrectomy performed on the same principle. Seeing that the operation is one which from ample experience I have found of great utility in all operations on the kidney I have no hesitation in describing it and recommending it to the notice of other surgeons. The accompanying diagram, which was drawn for me by my friend

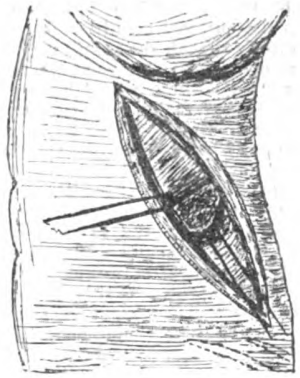

Diagram of incision, showing splitting and retraction of fibres of the external oblique muscle and also of internal oblique and transversalis.

Dr. F. Gairdner, who has assisted me in several of these operations, shows at a glance the principles on which the operation is based. The incision beginning to the inner side of the anterior superior spine of the ilium is carried backwards obliquely towards the tip of the last rib. The fibres of the external oblique and its aponeurosis are then split and retracted, exposing the internal oblique muscle, the muscular fasciculi of which are split in a line between the ninth costal cartilage and the posterior superior spine of the ilium, in which position they are longer than in front of or behind that line. When the fingers are pushed through the internal oblique to split it the fibres of the transversalis are pierced and can be retracted along with the oblique muscle. A

[1] A paper read before the Leeds and West Riding Medico-Chirurgical Society on April 22nd, 1898.

diamond-shaped space is thus formed, at the bottom of which is seen the transversalis fascia, which is then incised, exposing the peri-renal fat, and on pushing the fingers through this the kidney is easily reached in whatever position it may lie. If needful the whole hand may be introduced into the peri-renal space and the kidney can be grasped and freely manipulated, the retractors for the moment being withdrawn. If the vessels are moderately long, and in all cases of moveable kidney, the organ may be brought through the wound and explored by incision or by needling or it may be examined by the selenium screen and the Roentgen rays. Should a calculus be found it can be extracted and the wound sutured before the organ is returned, as in the following cases reported for me by my house surgeon, Mr. Dobson.

CASE 1.—A woman, aged sixty-nine years, had suffered from attacks of pain in the left lumbar region for several years and from acute continuous pain for the last three weeks, with pyuria, vomiting, and constitutional disturbance. A tumour could be felt in the renal region, tender, moveable, and dull on percussion, the dull area being crossed by a resonant band. On Feb. 11th, 1898, the operation as described above was performed and four stones were removed from the dilated kidney, together with a quantity of pus. Drainage was effected through a stab wound in the loin and the original wound was closed. The wound healed by first intention and the tube was removed in a week. She was made an out-patient on March 1st and was shown at the clinical meeting of this society on March 4th.

CASE 2.—A woman, aged sixty years, had passed renal calculi six and three years previously and for eight weeks before I saw her was feeble and ill, suffering from pyuria with bladder irritability. The symptoms were referred altogether to the bladder, but the left kidney was enlarged and tender. On April 11th I exposed the kidney by splitting the muscle and brought the kidney out of the wound. It was sacculated and contained purulent urine, but the ureter was free from obstruction. An oxalate stone with sharp projections was excavated from the top of one of the calyces through a free incision along the dorsum of the kidney, bleeding being arrested by compressing the renal artery. The wound in the kidney was then sutured by catgut stitches passed deeply, after which the kidney was returned and a drainage-tube passed down to the neighbourhood of the renal wound in case of leakage. The tube was removed on the third day, when the rest of the wound was found to be healed. The bladder irritability has subsided and the patient so far as the surgical condition is concerned is progressing satisfactorily though she is still very weak.

CASE 3.—A woman, aged thirty-one years, was admitted to the infirmary with a three years' history of attacks of pain in the right lumbar region radiating to the thigh and across the abdomen. She had had hæmaturia on several occasions. During the last few months the attacks had been very severe with vomiting and collapse. On April 21st, 1898, the kidney was exposed by splitting the muscles and was drawn through the wound, when a calculus was felt in the pelvis of the kidney which was exposed on its posterior aspect. The stone, which weighed 18 grains, was of about the size of a wren's egg and after its removal the wound in the pelvis was sutured by catgut, a drainage-tube being inserted into the peri-renal space. The patient has thus far progressed satisfactorily. Should it be found necessary to drain the kidney or its pelvis it is easy to make a stab wound through the loin and to pass a tube through that into the wound in the kidney, as in the following case.

CASE 4.—I was asked by Mr. Roberts of Knayton to see a woman, aged thirty-five years, suffering from a tender swelling in the right renal region, but without any marked urinary symptoms except a little pus and albumin in the urine. The symptoms had come on after a period of gradual failure of health and had been acute for eight weeks. When I saw her the temperature was 103° F. and the pulse was rapid and feeble. She was brought to a surgical home and the kidney was exposed by splitting the muscles. Offensive pus was found round the kidney, the kidney itself being swollen and containing pus. The kidney was drained by a tube passing through the loin and the upper wound was sutured. Except where the tube was the wound healed by first intention and at the end of a fortnight, the discharge having ceased, the tube was left out. She returned home on the twenty-first day and has progressed satisfactorily since. Should no disease be found beyond preternatural mobility sutures can be passed through the kidney substance when it is exposed, and then, on returning it, they can be passed through the tissues in the loin so as to anchor it securely as in the following case.

CASE 5.—A woman was sent to me by Mr. Reynolds of York with a very moveable left kidney producing all the symptoms of calculus. The pain was paroxysmal and was followed by albuminuria, which passed off between the attacks. The kidney was exposed and brought out of the wound, but a thorough exploration of it and the ureter revealed no stone. Sutures were passed through the kidney substance and then the kidney was returned and the stitches made to transfix the tissues in the post-renal region and to fix the kidney there. Healing occurred *per primam* and she returned home within the month.

Should no calculus be found and no disease involving further operation on the kidney the ureter can be explored even to its termination in the pelvis by an extension of the opening downwards and by means of a search light. When the peritoneum is well retracted the tube may be seen along its whole course, as in the following case.

CASE 6.—A man, aged thirty-nine years, was admitted to the Leeds Infirmary in October, 1897. He had been subject to attacks of pain in the loin for four years radiating along the course of the genito-crural nerve. There were irritability of the bladder, hæmaturia, &c., so that all who saw him suspected stone in the left kidney. The kidney was palpated and explored and the ureter was examined along its whole course, but without any stone being found. In this case, after exposing the kidney, the lower fibres of the internal oblique were divided to the extent of about three inches, in order to give more room to see the vesical end of the ureter. He was made an out-patient on Nov. 30th and has remained well and free from his attacks.

Cases 7, 8, and 9 afford other examples of negative exploration.

CASE 7.—The patient, aged thirty-four years, had had radiating renal pain for five years, hæmaturia, &c. On Jan. 20th, 1898, exploration of the kidney and ureter by an anterior oblique incision was performed. The result was negative as to calculus, but up to the present relief to all the symptoms. He was made an out-patient on Feb. 9th.

CASE 8.—The patient, aged thirty-six years, had had pain for six weeks in the left lumbar region, coming on in attacks radiating down the thigh and across the abdomen. There was pain on percussion over the kidney and the patient was said to have had hæmaturia. On Jan. 27th, 1898, an anterior oblique incision was made and the kidney and ureter were explored. The result was negative as to stone. She was made an out-patient on Feb. 26th.

CASE 9.—The patient, aged twenty-four years, had had renal pain, hæmaturia, &c., for fourteen months. On March 12th, 1898, exploration by an anterior oblique incision and splitting of the muscles was performed. The result was negative as to stone, but there was no return of pain. He was made an out-patient on March 22nd.

If the disease prove too extensive for simple nephrotomy it is quite easy to ligature the pedicle and perform complete nephrectomy, as in the following case, which I saw early last year.

CASE 10.—The patient was a woman, aged fifty years. She was suffering from hæmaturia with enlargement of the right kidney, which on exposure proved to be extensively invaded by malignant disease. The kidney was easily drawn through the wound and removed, recovery being uneventful.

In case the disease of the kidney is only partial the complete exposure enables a conservative operation to be done, as in the following example of partial nephrectomy.

CASE 11.—A woman, aged fifty-eight years, was sent to me by Mr. Wilson of Kirkby Overblow for tumour below the right costal margin accompanied by marked loss of flesh and great pain. Exploration revealed a tumour of the upper end of the kidney which was removed by excising a wedge-shaped piece of the upper end of the kidney including the tumour; bleeding, which was very free, was easily arrested temporarily by compressing the renal vessels and the kidney being outside the wound offered no difficulty to manipulation. On bringing together the V-shaped aperture by catgut sutures passed deeply, bleeding was completely arrested, and although a drainage tube was inserted as a precaution it was removed on the second day. The wound healed by first intention and the patient rapidly regained her flesh and strength and is now well.

After all necessary manipulations on the kidney have been

effected, the kidney, if not removed, is replaced, or if not disturbed from its bed is left *in situ*. The cavity is then sponged out and on withdrawing the retractors the muscles at once fall together and may if thought desirable be sutured with two or three interrupted catgut sutures, the skin incision being brought together by interrupted silkworm gut sutures. As a rule, not a single ligature is required, as there is no bleeding.

The advantages of this method of exploring the kidney are obvious. 1. There is no division of muscle and therefore no weakening of the abdominal wall immediate or remote. 2. No vessels are divided, thus not only saving time but rendering healing *per primam* more likely. 3. No nerves are severed and therefore paralysis of the rectus and other muscles is avoided. 4. The operation is done with the patient lying on the back, to the great convenience of the anæsthetist, the operator and his assistants, and to the manifest advantage of the patient, who is saved much unnecessary disturbance. 5. The great saving of time as well as the diminution of hæmorrhage means lessening of shock, thus rendering operation feasible when it otherwise might be questionable. 6. It is an important fact that diagnosis in kidney cases, especially in renal calculus, is by no means perfect, and if it can be proved that an exploration of the kidney can be done quickly with little or no danger and without any subsequent weakness being left, the physician will be less loth to permit and the surgeon to perform an exploratory operation after all other means have been fruitlessly tried. 7. Lastly, after such an operation convalescence is materially shortened as the patient may be safely allowed to be up at the end of the second week or even earlier, since there is no fear of the wound giving way.

I may take this opportunity of saying that wherever I can when operating away from the middle line of the abdomen I make use of the principle of splitting instead of dividing muscles—for instance, in gastrostomy, in inguinal colotomy, in typhlotomy, sometimes in cholecystotomy, and nearly always in removal of the vermiform appendix. I would also point out that if it be found necessary to extend the opening—for instance, in case of operation on the ureter—deeply in the pelvis it is easily accomplished by departing slightly from the principle here advocated and dividing the deep plane of fibres and further splitting the external oblique towards Poupart's ligament. The internal oblique will then require suturing to bring together the divided edges. In this way the ureter, even to its entrance to the bladder, may be fully exposed to sight as well as touch, as in a case which was witnessed by my colleagues, Mr. Teale and Mr. Ward, who will, I feel sure, bear me out in my statement as to the efficiency of this method of exploration. I could relate a greater number of cases on which I have operated, but I think that those I have given will be sufficient to serve as examples.

Leeds.

PUERPERAL ECLAMPSIA.[1]

BY THOMAS G. STEVENS, M.D., M.R.C.P. LOND., F.R.C.S. ENG.,

OBSTETRIC PHYSICIAN TO THE SURREY DISPENSARY; LECTURER ON ELEMENTARY BIOLOGY, GUY'S HOSPITAL.

PUERPERAL eclampsia is now understood to mean convulsions with loss of consciousness unconnected with gross cerebral or spinal lesions in parturient women. The frequency of its occurrence is variously stated by writers, but in all probability about once in 260 labours[2] is the usual proportion. With regard to the period at which convulsions come on, the greater number occur before labour commences, then in order of frequency during, and, finally, after labour.[3] All statistics do not show this; but it must be remembered that appearances are sometimes fallacious, the onset of the convulsions being so closely followed by labour that the two phenomena have been supposed to be synchronous. Cases have been recorded at all periods of pregnancy from twelve days upwards; by far the greater number occur between the seventh and eighth months. Premonitory signs usually are present, but often are not taken much notice of. The commonest are headache, disturbances of vision, flashes of light before the eyes, amblyopia or even blindness, ringing in the ears, dyspnœa, tingling and numbness of the limbs, and, a very important sign, epigastric pain very similar to the pain complained of before diabetic coma supervenes. Occasionally diminution, steady and gradual, in the amount of urea eliminated by the kidneys has been noted and this has been used as an argument by some for the routine examination of the urine from time to time in parturient women, especially in primiparæ.

There is nothing resembling the aura of epilepsy in these cases. The phenomena resemble those of true epilepsy, but there is no epileptic cry. The tonic stage is very short, lasting only from half to one second, and is rapidly succeeded by the clonic with its usual stertor, jerking of muscles, and irregular respiration. This stage lasts for a minute as a rule, but may be prolonged to five minutes. Coma of variable duration succeeds the clonic stage, and then the patient recovers. On the other hand, consciousness may not be recovered before a second convulsion begins, this perhaps to be followed by others, even as many as 100 convulsions having been recorded in one patient. The temperature generally rises with each attack; this is said to constitute a differential diagnosis between eclampsia and uræmia from Bright's disease, in which the temperature usually but not invariably falls.

Eclampsia is always associated with albuminuria. I am aware that statements have been made to the contrary, but I feel sure that albuminuria will always be found at least just before and during the attack, though the next day, if convulsions have ceased, it may also have disappeared. In all the cases of eclampsia in the Guy's Hospital Lying-in Charity in which the urine was examined during the forty years up to 1875 albumin was only absent in two,[4] and in one of these the convulsions were due to meningitis; in the other they came on after severe post-partum hæmorrhage in a girl who had been seduced. It must be borne in mind that all parturient albuminurics do not get eclampsia; indeed, it is exceedingly rare to see eclampsia follow on the chronic albuminuria of pregnancy, and as a general rule a patient with dropsy and albuminuria during pregnancy may be confidently told that she will not get eclampsia. The urine may be scanty or even suppressed at the onset of the convulsions. The uterus is usually excited to contract but does not share in the irregular muscular contractions, though Braxton Hicks stated that it may become tetanic. In about 50 per cent. of the cases the fœtus dies before delivery, either because labour terminates before the fœtus is viable, or the fœtus is poisoned by the same cause which produces the eclampsia, or is asphyxiated on account of deficient oxygenation of the blood or separation of the placenta by hæmorrhages.

Terminations.—Complete recovery may occur without special treatment if delivery is completed soon enough; on the other hand, death may occur in spite of treatment from any of the following causes: acute toxæmia leading to heart failure; gradual asphyxia due to accumulation of secretions in the bronchi; pneumonia; puerperal sepsis due to infection during the hurried treatment often adopted. The albuminuria generally disappears quickly in cases which recover, but not uncommonly grave renal disease persists after the attack.

Diagnosis has to be made from true epilepsy which is not accompanied by albuminuria, has not the same prodromata, is not associated with a rise of temperature, and, as a rule, has a definite history of previous attacks; from meningitis which is accompanied by vomiting, optic neuritis, opisthotonos, and rise of temperature before the convulsions; and from hysteria which is not accompanied by albuminuria, never by incontinence of urine or fæces, in which unconsciousness is rarely absolute, and in which there is no rise of temperature, and the movements of which are very irregular and do not as a rule in the least resemble epilepsy.

Prognosis is most difficult in those cases in which the fits begin before labour; but even here, if the number of fits is less than fifteen, the coma not very profound between the fits, the pulse not too frequent or the temperature not very high, and, above all, rapid and safe delivery is possible, the prognosis is

[1] A paper read before the Æsculapian Society on Dec. 3rd, 1897.
[2] Vinay: Traité des Maladies de la Grossesse, Paris, 1894.
[3] Herman: Transactions of the Obstetrical Society of London, 1892.
[4] Galabin's Midwifery.

generally fairly good. According to Duhrssen[5] in 93 per cent. of the cases the fits cease after delivery. Deep œdema, constantly recurring convulsions, slowly progressing labour, especially combined with anæmia and a bad pulse, always put a very serious aspect on the case.

Post-mortem appearances are very inconsistent and apparently there is no known lesion constantly associated with eclampsia. In a large proportion of cases the kidneys are affected; a parenchymatous nephritis is found sometimes associated with very acute congestion. In some cases the brain shows minute hæmorrhages and anæmia, rarely hyperæmia. The liver is sometimes markedly pathological, small hæmorrhages, areas of necrosis, and sometimes even complete disorganisation of structure being present. In all probability these changes are secondary and stand in no way in causal relation to the disease.

Etiology.—The causation may be classified under three heads: predisposing causes, essential causes, and exciting causes. Among the predisposing causes primiparity (the disease is seven times more common in primigravidæ than in multigravidæ) and twin pregnancies probably act in the same way by giving a greater tendency to albuminuria and renal inadequacy due to increased work thrown on the kidney. Heredity as a cause is very doubtful. Then there are the mental disturbance and increased irritability of the nerve centres in pregnancy. The essential causes must be carefully distinguished from the chronic conditions which produce albuminuria, for, as has been shown, chronic albuminuria in pregnancy, whatever its cause, is very unlikely to give rise to eclampsia. The older theories, such as the cerebral anæmia theory of Traube and Rosenstein, the cerebro-spinal congestion theory, the uræmic theory, and countless others are now given up. No one now contends that uræmia is due to retention of urea in the blood, for large quantities of urea may be injected into the blood-stream without producing convulsions. A microbian theory has, of course, been suggested, but no microbe has been isolated and in any case the microbe could only be proved to be the source of the toxins which are now generally accepted as the cause. The toxæmic theory suggests that the symptoms are due to the retention in the blood of poisons usually eliminated by the kidneys. The clinical picture lends colour to this theory, consisting as it does of prodromata, action of the nerve centres, and inflammatory sequelæ. The analogy of such diseases as diphtheria and typhoid fever also supports this view. What is the source of the toxic agents? It has been proved that normal urine contains several toxic principles and Bouchard[6] has shown that in eclampsia these are decreased in the urine and that the toxicity of the blood is increased. If the blood becomes supersaturated with these principles owing to renal incompetence (not necessarily inflammatory but simply physiological) intoxication results and eclampsia appears. The poisons may be maternal but from what source we do not know. They may also be fœtal, for we know certainly that in some cases when the fœtus dies the eclampsia ceases. The important point to realise is that these toxic principles are in all probability physiological products of normal organs, and as such their origin may be in the muscular system, in the viscera, or anywhere in fact where active metabolism is going on. The exciting causes may be very slight. Given the supersaturation of the blood with toxic principles, a slight stimulus such as a uterine contraction, a mental fright, the passing of a catheter or the giving of a rectal enema, or even the making of a vaginal examination, may be sufficient to upset the balance.

Treatment is based on the assumption of the toxæmic theory above described and may be divided into two categories: first, the treatment of the cause of the disease and, secondly, the treatment of the convulsions themselves. The first, of course, is the more important and briefly put consists in aiding nature as far as possible to eliminate the poisonous toxic principles from the body. The usual avenues for the elimination of excretions are the skin, the kidneys, and the bowels. We can stimulate either of these to increased action, and if the kidneys are inadequate the extra action of the other two may be made to compensate somewhat. To stimulate the skin and to promote diaphoresis we use the hot bath at 100° F., or the hot vapour or air bath, or the hot wet pack. I need not go into the questions of how to give these. I do not believe in drugs to induce sweating, and especially *not* pilocarpine. It is a dangerous drug to use in these cases on account of its depressing action on the heart and the danger of asphyxia from the large amount of bronchial mucus it produces. Drugs by the mouth of course are contra-indicated because the patient is usually unconscious. As the urine is unusually scanty, and the kidneys are probably deeply congested active measures must be taken to relieve these. An old-fashioned but very efficacious remedy is dry cupping to the loins, followed by linseed meal poultices. Infusion of salt water (1 dr. to the pint) into the veins or subcutaneous tissue is very useful in promoting diuresis. In many of these cases the circulation is at very high tension as shown by plethora and the very hard pulse; this condition by itself greatly embarrasses the action of the kidney (or possibly the inadequate kidney really produces it) and I am confident that for such a condition there is nothing to compare with bleeding. It acts by relieving the circulation and lowering the tension, by diminishing the congestion of the kidneys, and very probably also by removing some of the toxic principles from the blood. The quantity of blood removed should not exceed 20 oz. I have twice used bleeding in typical cases and both times the result was all that could be desired, the pulse became slower and the tension was relieved, and the fits stopped entirely and did not recur Bleeding must not be employed when the patient is anæmic or when the circulation is feeble. The time-honoured treatment for the bowels is to give two minims of croton oil, but I am bound to say that this does not always have any effect. Any drug which can be given to an unconscious patient and which will produce a liquid motion may be used and will help to relieve the circulation. With regard to the treatment of the convulsions the patient must be prevented from hurting herself through falling out of bed or biting her tongue. Chloroform must be given by inhalation and light anæsthesia may be continued for hours, increasing the dose if a fit seems to be coming on. As an alternative to chloroform morphia has been largely used of late years at the Rotunda Hospital, Dublin. It is given hypodermically in full doses until the full effect is reached and it is claimed that the results have been better since chloroform has been abolished. There need be no fear of giving morphia on account of the renal complication. It does not seem to matter whether the kidneys are sound or not; indeed, morphia is largely given nowadays in chronic Bright's disease. Besides these bromide of potassium is generally given with or without chloral hydrate by the rectum—from 30 or 60 gr. of the former, 30 gr. of the latter—but very little good could be expected from them alone. My own experience of these drugs is limited to chloroform, but my cases are too few and too uniformly happy in their ending to be able to say much about it.

To my mind there can be no doubt that labour should be induced where eclampsia precedes. I am convinced that nothing gives the mother a better chance of recovery than a rapid but safe and deliberate delivery. No forced delivery should be attempted, the greatest care must be taken not to produce tears, and above all the strictest antiseptic precautions must be taken; for a patient recovering from eclampsia is in the worst possible condition for withstanding septic microbes and therefore is more prone to septicæmia than other presumably less worn out patients. Nothing could be more miserable than to pull a patient through an attack of eclampsia only to see her succumb to the ubiquitous streptococcus. The greatest success in these cases will be with him who carries out all these methods of treatment, not hesitating to pile up one upon the other until the disease is checked.

As a routine treatment for a given case I would suggest the following. Give chloroform or keep the patient under morphia and also give the bromide and chloral *per rectum*. Protect the patient from injury. Induce labour. Bleed if the pulse is hard and the patient is plethoric. Give a hot wet pack or bath. Dry-cup the loins and then put on linseed meal poultices. Give two minims of croton oil on a bread crumb placed on the tongue. In a large proportion of cases a good result will be obtained if treated in this manner. Even with all this treatment, however, there are, unfortunately, cases which do terminate fatally; but as far as we are concerned we cannot recognise them beforehand and so we must not omit one item of the treatment.

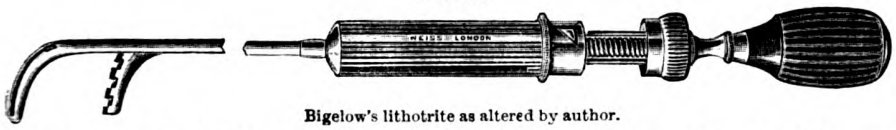
A RECENT SERIES OF 100 OPERATIONS FOR STONE IN THE BLADDER, WITH SOME PRACTICAL REMARKS THEREON.[1]

BY P. J. FREYER, M.A., M.D., M.CH.,
SURGEON TO ST. PETER'S HOSPITAL.



IT has now fallen to my lot to have performed 912 operations for stone in the bladder by all methods—viz., 249 perineal lithotomies, 7 suprapubic lithotomies, 1 vaginal lithotomy, 3 removals of stone from the female bladder by rapid dilatation of the urethra, and 652 litholapaxies. Full particulars of the great majority of these operations, as to age of patients, weight of calculus, mortality, &c., have appeared in papers published by me in the various medical journals during the past sixteen years and in the recent edition of my work "The Modern Treatment of Stone by Litholapaxy."[2] It is, however, to my latest series of 100 operations for stone in the bladder that I propose inviting attention. I may at once say that these operations were one and all successful. I propose giving some brief statistics of these operations, describing the methods by which the results were obtained, and, by reference to important individual cases, directing attention to some practical features in the modern operation for stone.

I have now for several years practically abandoned all other methods of dealing with stone in the bladder in favour of Bigelow's operation. The force of this statement will be brought home when I say that amongst this series of 100 operations there were only 2 lithotomies, the remaining 98 cases having been dealt with by litholapaxy. In one of these two cutting operations—a case in private practice—the suprapubic method was adopted for the removal of these two calculi contained in this cystic tumour which projected into the bladder and presented on cystoscopic examination the appearance of a fibro-papilloma. Details of the case, which I believe to be unique in the annals of surgery, were placed before the Royal Medical and Chirurgical Society in November last and are published in the Transactions of that society. The other case was that of a patient in St. Peter's Hospital, who, in addition to stone, suffered from severe stricture of the urethra with perineal fistulæ. Median lithotomy was performed, the stricture at the same time being successfully dealt with. Amongst the remaining 98 cases operated on by litholapaxy there were 94 males and 4 females; 68 were adults and 30 were male children or lads under seventeen years of age.

Litholapaxy, as you are aware, consists in the rapid crushing of the stone and the complete removal of the fragments at one sitting. Crushing of calculi at numerous "sittings," or lithotrity, had been more or less in vogue from the early part of the century, finding its ablest advocates in Civiale in France and Sir Henry Thompson in this country; but the essential part of the modern, or Bigelow's, operation consists in the complete removal of the fragments at one sitting. Undoubtedly one of the most, if not the most, essential elements of success in this operation is the employment of proper instruments. Time will not permit of my going into that interesting subject—the history of the development of these instruments. I will therefore confine myself to a brief description of the instruments employed in my own practice at the present time.

The lithotrite shown in Fig. 1 was made for me in

FIG. 1.

Bigelow's lithotrite as altered by author.

1886 by Weiss and it is the model on which all my lithotrites have since been constructed. It contains the handle and locking action of Bigelow with fully fenestrated blades instead of a non-fenestrated female blade as originally used by Bigelow. The ball handle affords a much firmer grip to the hand than the old-fashioned wheel—a grip which is essential when dealing with large and hard calculi. The locking action is of the simplest character, the instrument being locked and unlocked by a quarter turn of the cap to the right or left by the right hand, the left hand being free to grasp the female blade and to hold it steady in the bladder during the various manipulations. The female blade is fully fenestrated, smooth, and bevelled on the inner aspect of the slot, so that it is almost impossible to catch the mucous membrane. I use none but fully fenestrated lithotrites in my practice now, regarding the use of any other kind—whether non-fenestrated or partially fenestrated—as dangerous, owing to the liability which exists with them of débris getting impacted in their jaws—an accident which cannot occur with a fully-fenestrated lithotrite when properly used. To cope with calculi of all sizes and consistencies in patients of all ages a series of lithotrites varying from No. 4½ to No. 18 of the English scale should be at hand. Bigelow's original aspirator, though efficient, was both complicated and cumbersome and has been modified from time to time by himself and other surgeons. This form of Bigelow's aspirator, simplified

FIG. 2.

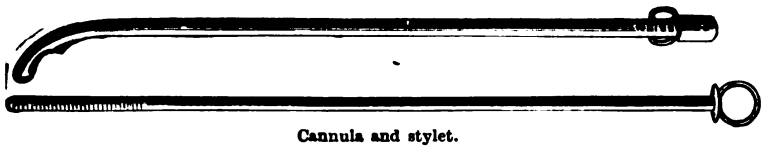
by myself and others, I worked with for years and found thoroughly efficient. I have still further simplified this by dispensing with the tap above the rubber bulb, which is quite unnecessary, as the apparatus can be easily filled by immersing it in a basin of water. The essential requirements, to my mind, in a perfect aspirator are: (1) that the apparatus be light and handy, so that when attached to the cannula in the bladder it can be moved about freely in any direction by one hand; (2) that the distance between the rubber bulb and the bladder be the shortest possible and the intervening course of the fluid as nearly straight as possible; (3) that the rubber be strong and pliant, so as to give sufficient suction power; and (4) that fragments once entering the receiver cannot return to the bladder. These attributes my new aspirator (Fig. 2) possesses. I have now worked with it for more than two years and have found it thoroughly efficient in all respects.

The cannulæ vary in size from No. 6 to No. 18 of the English scale, those from No. 6 to No. 11 being necessary for male children and those from No. 12 to No. 18 for adults and females of all ages. Cannulæ are either straight or curved. Those which I use (Fig. 3) are slightly curved at the end to facilitate their introduction. They should be armed with stylets, which should be introduced before withdrawal of the cannula from the bladder, so as to prevent a fragment getting impacted in the eye, which would tear the urethra or possibly get dislodged in that canal.

The calculi, the débris of which I show you, varied in weight from a few grains to over 3 oz., the average weight in adults being 226 gr. and in children 79 gr. The case in which this large stone, composed mainly

[1] A paper read before the Harveian Society of London on April 28th, 1898.

[2] Baillière, Tindall, and Cox, 1886.



of oxalate of lime and weighing 3 oz. and 20 gr., was removed is interesting, so I will give the details briefly.

The patient, a man, aged thirty-four years, was sent to me by Mr. William Armstrong of Buxton. He had suffered from childhood from symptoms of stone, and had on two occasions been unsuccessfully sounded before coming under Mr. Armstrong's care. On April 29th, 1897, assisted by Mr. J. G. Pardoe, Mr. Woodhouse Braine giving the anæsthetic, I crushed and evacuated in twenty-four minutes this large and hard stone. Two days after the patient wrote to Mr. Armstrong saying that he did not know why he was being kept in bed. He was walking about his room on the fifth day, and he left the surgical home on May 9th perfectly well. This was one of the hardest and sharpest pieces of work I have ever performed. My hands were blistered from the lithotrite and my arms ached for days after the operation. I need scarcely say that it requires much practice to deal so rapidly with a large and hard stone like this. It is, I believe, the largest stone that has been removed in England by litholapaxy, though in India I have successfully removed by this method a urate stone more than twice this weight,[3] and still larger stones have been removed in India and in Egypt.

I attach the utmost importance to the rapidity with which large calculi can be removed by litholapaxy. As a rule in such cases the patient's health is broken down and the kidneys are affected. Under such circumstances prolonged narcosis leads to congestion of these organs, exhaustion of the vital powers and shock. Other things being equal I venture to say that our success will vary in inverse proportion to the length of time spent over the operation.

The average age of the adults was fifty-one years and of the children or lads under the age of seventeen years six years. The youngest child operated on by me in England was one aged one and a half years, sent by Mr. Dartnell of Rochester. The child had suffered for two and a half months from the usual symptoms of stone in the bladder. On Feb. 9th, 1897, Dr. Dudley Buxton giving the anæsthetic,

FIG. 3.

Cannula and stylet.

I removed in six minutes a calculus, weighing 9 gr., composed of an oxalate of lime nucleus covered by phosphates. A No. 6 lithotrite and a No. 7 cannula were passed with ease. During the day the child had some scalding in passing urine. Next day I had the pleasure of seeing him with my friend Dr. John Anderson, C.I.E. The child was playing on the floor quite well and he left the surgical home on Feb. 13th. This is, as far as I am aware, the youngest male child on whom litholapaxy has been performed in England. The oldest patient of the series was a man, aged eighty-five years, suffering from a hypertrophied prostate, from whom I removed by litholapaxy, at St. Peter's Hospital, on Feb. 17th, 1897, a small prosphatic stone weighing 18 gr. This patient recovered without a bad symptom and was discharged on the sixth day. Amongst the series there were 4 females—1 child and 3 adults—litholapaxy being the operation performed in each case, the weight of the calculi ranging from 17 gr. to 290 gr.

A recent case in which I removed a stone from the bladder of a female presented such an excellent clinical picture that I am tempted to give brief details thereof. The patient, aged forty-four years, had suffered for four years from attacks of renal colic, gradually increasing in frequency and intensity. About a month before I was called in a large moveable tumour developed in her left loin, accompanied by pyrexia. Pyonephrosis the result of impacted stone in the ureter was the diagnosis arrived at by her medical attendant and this view of the case was confirmed at a consultation with Dr. Sidney Ringer. Exploration of the kidney was considered advisable but shortly after the consultation the patient passed suddenly over 50 oz. of pus and urine, when the tumour and pyrexia subsided. A day or two after symptoms of stone in the bladder supervened and continued till April 1st, 1898, when I was called in. The patient being anæsthetised by Dr. Dudley Buxton, Dr. Ringer being present, I at once detected a stone in the bladder on sounding. Its crushing and removal by the aspirator were the work of a few minutes. The débris was composed of an oxalate of lime, dumb-bell shaped nucleus, covered by urates and phosphate of lime, and weighing 33 gr. The patient was up and walking about on the fourth day and is now perfectly well, free from all kidney and bladder symptoms.

Bigelow's operation in females is comparatively easy, the instruments employed being the same as for males. The only special difficulty sometimes met with is that, owing to the width and shortness of the urethra, the water which is necessary in the bladder during the crushing of the stone is liable to rush out beside the instruments. This difficulty is obviated by getting an assistant to place the fore and middle fingers of one hand in the vagina and to press the posterior lip of the urethra against the lithotrite, a manœuvre which prevents the water flowing out. Litholapaxy is eminently successful in females, the patient being, as a rule, able to walk about in a day or two after the operation. One of the most terrible afflictions that a woman can suffer from is permanent incontinence of urine; but how frequently do we find this condition after removal of stone by "rapid dilatation of the urethra." In my pre-litholapaxy days I had one such case in my own practice and I have come across several such in the practice of other surgeons, one quite recently. Bigelow's operation obviates the occurrence of this dreadful affliction, as no preliminary dilatation of the urethra is necessary for the introduction of the requisite instruments.

The time spent in hospital or under treatment in case of patients in private practice after the operation of litholapaxy varied from 2 days to 20 days, the average being a little less than 8 days. But in many instances the patients were kept two or three days longer than necessary under treatment as a precautionary measure. Contrast this period of days with the period of nearly as many weeks required after lithotomy, whether perineal or suprapubic.

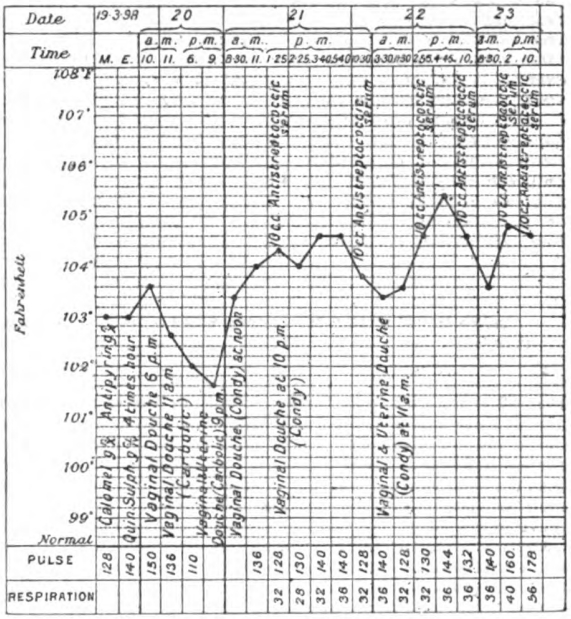
These 100 operations were performed on 99 individuals, there being only one case of recurrent stone in my own practice—a man, aged eighty-four years, a patient under the care of Dr. John Anderson, with an enormous prostate. In May, 1897, I removed a small urate stone and again in February, 1898, a phosphatic stone weighing 92 gr. Three of the patients had litholapaxy performed previously by other surgeons, but in one instance only was the recurrence due to a fragment having been left behind at the previous operation. In one instance also suprapubic lithotomy had been performed by another surgeon.

It will be within the knowledge of many that the greater portion of my experience in this branch of surgery was acquired in India; it was in India that I performed my first litholapaxy, and it was in that country, with its splendid facilities, that I learnt how to operate for stone. I may therefore be asked, and rightly asked, Is there anything peculiar in the climate of India or in the constitution of the native of that country which renders him a better subject for litholapaxy than the European? To both these questions I answer emphatically in the negative. In the first edition of my work on Litholapaxy I collected statistics of 2592 lithotomies performed in the public hospitals in India in 1882 and found that the mortality was 13 per cent., which is practically the same as that (12½ per cent.) occurring amongst 1827 lithotomies in public hospitals in England, the statistics of which were collected by Sir Henry Thompson. But if the native of India is not a better subject for lithotomy than the European I am unable to comprehend by what method of reasoning it is alleged—and I observed that this has been persistently alleged in the medical journals—that the former is a better subject for litholapaxy than the latter.

I am now, however, in a position to speak with authority in this matter, having had considerable experience of this operation both in India and in England. Last year I had 29 operations for stone in the bladder and during the short period since I settled in practice in London I have performed 45 operations—viz., 43 litholapaxies and 2 lithotomies, all of which were successful.

I find, however, that there are some interesting features of contrast between my practice in India and in England. In the first place I find that the average age of 40 adult Europeans operated on by me is fifty-six years, nearly eleven years greater than the average age in the adult natives of

[3] Brit. Med. Jour., June 16th, 1894.



India. Mr. Cadge of Norwich, in his article on "Lithocrity," &c., in Heath's "Dictionary of Surgery," in contrasting the results obtained in my first series of 108 litholapaxies performed in India with a somewhat similar series of cases by Sir Henry Thompson in England notices this marked difference in the average age. It is simply due to the fact that the "expectation of life" in India is probably about ten years less than in England, a native of India being at fifty years of age comparatively as old as a European at sixty years of age. Secondly, the average weight of the calculi removed by me from adults in London is 149 gr. as compared with an average of 309 gr. in India. This is a point to which Mr. Cadge also called attention in the article referred to, the average weight of the calculi removed by me in India in the series referred to having been nearly two and a half times greater than that of the average of Sir Henry Thompson's series. Thirdly, the very much larger proportion of prostatic patients met with in England than in India. Before I commenced practice in London my friends and present colleagues at St. Peter's Hospital, Mr. Reginald Harrison and Mr. Swinford Edwards, frequently said to me that they believed that in the surgery of stone one met the complication of hypertrophy of the prostate much more frequently in England than in India. In holding this view I find they were perfectly correct, for amongst 39 adult males on whom I performed litholapaxy in England there were 13 suffering from hypertrophy of the prostate, or one-third of the whole, a very much larger proportion than one meets with in India and which may to some extent account for the much larger number of recurrences of stone met with in England than in India. It will be noticed that in no instance in this series was the coexistence of hypertrophy of the prostate with stone a bar to the performance of litholapaxy, though in many instances there was very great enlargement of the gland present.

Harley-street, W.

A CASE OF PUERPERAL FEVER TREATED WITH ANTISTREPTOCOCCIC SERUM; DEATH.

BY J. PAUL ROUGHTON, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H.,
SURGEON TO THE KETTERING GENERAL HOSPITAL,
AND
ARNOLD G. TOLPUTT, M.R.C.S. ENG., L.R.C.P. LOND.

A WOMAN, aged twenty-seven years, gave birth to her sixth child on March 16th, 1898, at 12.45 P.M. Mr. Tolputt arrived at 1.10 P.M. and expressed the placenta with ease, the placenta and membranes being complete. Very little hæmorrhage occurred. On the 17th the patient's condition was satisfactory in every respect. On the 18th she was not visited, but on the 19th the nurse stated that she was "feverish" and flushed and complaining of faintness, and that the diapers were noticed to be "slightly offensive and the discharge scanty." The patient was found to be breathing more rapidly than normal; the pulse was 128 and the temperature was 103° F. The bowels had been opened once. There was no headache. 10 gr. of antipyrin were given and 10 gr. of calomel half an hour afterwards, the bowels being moved three times and vomiting occurring twice. A pill containing 4 gr. of sulphate of quinine was given every four hours and was continued throughout the illness. A vaginal douche was given by a trained nurse in the evening. On the 20th the condition of the patient was much the same and we decided to inject antistreptococcic serum, but were unable to obtain the serum till the next day. The patient was apparently better in the evening. On the 21st the patient's condition in the morning was grave, although she had passed a good night. A large thrombus appeared in some varicose veins of the right leg. The abdomen began to be tympanitic. The pulse, respiration, and temperature were much raised and the tongue was covered with a dry white fur. She complained of being drowsy and was a little deaf. There had been no rigor. The lochia had ceased, but they reappeared in the evening, when there was very little fœtor. Milk and beef-tea were taken in good quantities and were well retained. At 1.25 P.M. the first injection of 10 c.c. of Messrs. Burroughs and Wellcome's antistreptococcic serum was made in the abdomen, the most strict antiseptic precautions being taken in every detail. We saw the patient again an hour afterwards and practically no change had occurred in her condition, but she had slept a little. An hour later she was still drowsy; the temperature was a little higher. At 10.30 P.M. a vaginal douche was given, followed by another injection of 10 c.c. of serum; we then found the patient's state practically the same, but the condition of the tongue was much improved; the abdomen, however, was becoming more distended. In the night she was delirious at intervals and diarrhœa supervened, the bowels being opened nine times. On the 22nd in the morning the patient was worse, the abdomen was much more distended, and the clot in the veins had extended up to the groin. The lochia had altogether ceased. A vaginal and intra-uterine douche was given and an opium pill (½ gr.) was administered. The tongue continued to clean and there was

no headache and no rigor. She complained much of "wind." She continued to take nourishment well. At 2.55 P.M. 10 c.c. of serum were again injected and apparently had no beneficial effect whatever beyond keeping the tongue clean and the patient quiet. The condition of the patient gradually became more grave; the abdomen was extremely distended and the motions began to be passed unconsciously and were very offensive. At 10 P.M. 10 c.c. of serum were again injected without any improvement. On the 23rd it was evident that the patient could not recover, but two more injections of serum 10 c.c. were given. Her condition, however, rapidly became worse and she finally died at 2.30 A.M. on the 24th.

In this case the serum seems to have been useless as regards saving the life of the patient, but her general condition was certainly ameliorated. There were no rigors and there was scarcely any headache; the tongue, too, was much improved. It was perhaps unfortunate that the serum could not be obtained sooner. The only cause assignable for the infection was the insanitary condition of the house, the water having been condemned a short time previously. Also the patient had had a bad attack of diarrhœa earlier in the week. We again wish to point out that besides the use of the serum the very strictest possible antiseptic precautions were taken both as regards the instruments used and the hands of the operators.

Kettering.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

RECURRENT MEASLES.

BY J. H. BATTYE, M.D. R.U.I.

IN view of the recent extensive epidemic of measles I should like to put on record the case of my daughter, aged seven and a half years, which to me is unique. I have described it to two or three other medical men, my seniors in the profession, and they all tell me that they have not met with one like it. On Feb. 17th, 1898, there came out on my daughter a very moderate crop of morbilli of the pinkish, mild variety, beginning on the face as usual. Her temperature was 101·5° F. She had very slight bronchial catarrh, but no sickness, headache, or malaise. The rash followed the usual course, spreading downwards in patches and reaching the legs by the morning of Feb. 19th, when there was distinct waning of the eruption on the face. The temperature was not taken that morning, as on the previous evening it had been only 98·6°. At 11 P.M. she was not so well; her temperature was 105° and I found that there was a distinct second crop of morbilli of the purple variety very copious over the face, neck, and upper part of the body, intense bronchial congestion and oppression of breathing, and some cyanosis of the lips; the pulse was 160 as near as I could count, and there was great intolerance of light from conjunctivitis but no delirium. During Feb. 20th the eruption spread over the rest of the body, scarcely a particle of the skin being untouched, but the bronchitis became less, expectoration more free, and the temperature in the afternoon fell to 103·4°, rising, however, to 103·8° at 10 P.M. There was no delirium during night or day. On Feb. 21st the rash was fading on the face, but was very dark over the body and legs. The temperature fell further from 101° in the morning to 99 8° at night. On Feb. 22nd the rash was fading rapidly in the morning; the temperature was 99°, the bronchitis was passing away, the lungs were clearing, and everything seemed going on quite normally towards recovery, when just after 9 P.M. I found that the temperature was 103·4°, and that there was a fresh crop of morbilli more papular than either of the two previous eruptions, but not nearly so extensive as the second, though more than the first. Like the two previous eruptions this travelled all over the body, but there was no exacerbation of the bronchitis during the third eruption. The temperature on Feb. 23rd was 101·4° in the morning, 99 6° at night, and on the next morning (Feb. 24th) 99°. It rose again in the afternoon to 100·8° and there seemed a slight increase of the last rash, but on the following morning (Feb. 25th) the temperature was 98·4° and the rash finally disappeared on the evening of Feb. 26th having been out for ten full days.

One curious point about my daughter's case is that she had all the premonitory symptoms of measles—coryza, vomiting, headache, and lassitude with a temperature of 101° on Jan. 20th, and was kept in bed for two days and at home for ten days but no eruption of any kind followed. I may also state that her brother had measles before her, the rash appearing first on Feb. 8th, and that she was allowed to go into his room as I felt certain that she had taken it while he was incubating, an opinion justified by the appearance of the rash in her case on Feb. 17th. Were the successive eruptions of morbilli due to repeated infections from her having been with her brother? There seems to be a great variety of opinion as to whether thorough disinfection is necessary after measles and also as to the duration of infection after eruption. Some maintain that the patient is free from infection one week after the eruption appears, others that the period is three weeks. For myself I regard thorough disinfection to be as necessary after measles as after diphtheria or scarlet fever and that no one is really free from infection till after three weeks from the time of eruption, and in this last contention I think my daughter's case fully bears me out.

On April 28th my daughter was attack d with varicella and again there were no premonitory symptoms whatever. The eruption has been rather copious, but she has never had a headache or lost her appetite all through.

Belgrave-road, S.W.

HYPERPYREXIA IN MALARIAL FEVER.

BY CHARLES LLOYD WORRALL, L.R.C.P. LOND., L.S.A.

ON March 29th, 1898, I was called to see a family suffering from malarial fever, and on arriving at the house about 11 A.M. I found that a child, aged three years and seven months, had had a convulsion about 8 A.M. that day and had not regained consciousness. The convulsion lasted about five minutes, the short duration being probably due to the patient having been put into a hot bath. When I examined the child she lay on her back breathing very rapidly but with no approach to stertor. The pulse was imperceptible and the brow and face were moist and clammy. In the axilla the thermometer registered 108·8° F.; in order to guard against possible error I shook the mercury down to subnormal and replaced the thermometer in the axilla, when it again registered the same degree. The history of the case was briefly as follows. On the previous day (March 28th) the little girl had been as lively as usual until sunset, when she complained of feeling tired. During the night she was very restless and thirsty, but complained of no pain, nor was there any vomiting. She did not take breakfast on the morning of the day I saw her and at 8 A.M. she went off into a fit as stated above. On finding the temperature so high I administered a dose of calomel and phenacetin and placed the patient in a tepid bath, with the result that the temperature came down to 103° in a very few minutes. The girl was then put to bed, whereupon in a few minutes the temperature rose again to 107° and in a few more minutes came down to 106°, and at this point it remained until I left, but unfortunately the patient died in about half an hour after my departure—viz., between 1.30 P.M. and 2 P.M.

During my experience of malarial fever, which extends over three summers, I have only seen one case with a similar temperature. That patient was a woman suffering from puerperal fever complicated with malarial fever; her temperature registered 107·6° on my thermometer and 107·8° on that of a colleague. My two colleagues, the hospital and district surgeons, tell me that they have never seen so high a temperature in malaria. Of the child's case being malarial fever I have no doubt as everything pointed to it—the season, the locality, and the fact that two more of the family were suffering at the same time from distinct malarial symptoms although mild. I may add in conclusion that in children I find that a dose of calomel and phenacetin as a rule acts like a charm in reducing temperature previously to giving quinine.

Barberton, South African Republic.

BORACIC ACID AND SALOL IN CYSTITIS.

BY ARTHUR H. BUCK, F.R.C.S. EDIN.

THE following case is probably of sufficient interest for publication on account both of the age of the patient and of the marked good effect of small doses of boracic acid and salol on bacterial urine.

In the beginning of last December I performed suprapubic lithotomy on a man, eighty-three years of age. This operation was selected in preference to lithotrity on account of (1) the size of the stone, (2) its hardness, and (3) the presence of a large prostate. The bladder was drained after the operation by a large tube for three days, by a No. 12 catheter through the wound for three days, and by a catheter through the urethra for fourteen days. There was practically no escape of urine except through these tubes. Cystitis was present before the operation and in spite of washing out three and four times a day there were bacteria in freshly-drawn urine three weeks after the operation. The urine was of a dull light yellow colour and was becoming more alkaline, varying in quantity from three to five pints. On the twenty-second day 10 gr. of boracic acid, and 3 gr. of salol were prescribed every four hours. Within two days the urine was acid, and in

a fortnight it had regained its normal characters, no albumin being present and no bacteria. The patient was up in a fortnight and out of doors within six weeks after the operation. He still continues well in every way, passing a catheter nightly to get rid of residual urine. The calculus measured 1¼ in. by 1¼ in.; it was composed of oxalate of lime and weighed 1 oz.

A CASE OF PERFORATED GASTRIC ULCER; OPERATION; RECOVERY.

(Under the care of Dr. SHARKEY.)

IT is somewhat difficult to estimate the mortality in cases of perforated gastric ulcer which have not been treated by laparotomy, but it has been stated to be 95 per cent., and we may take this number as rather an under-estimate than an over-estimate of the death-rate from this lesion, and indeed the chance of a localisation of the effused contents of the stomach can be but small. Cases of perforation of a gastric ulcer in which previously complete adhesions have formed with a neighbouring organ, such as the liver, belong to an entirely different category and should be excluded from the statistics founded on cases perforating into the peritoneum. The mortality after the operation was considered to be about 70 per cent. by Greig Smith,[1] but this opinion was founded on only about 100 cases; since that time the operation has been performed much more freely and at an earlier period after the perforation, and the death-rate has certainly improved. Laparotomy for perforation of an ulcer of the stomach was first suggested by Dobson[2] of Bristol, and the first operation was performed by Czerny in 1885, but the patient died. This unsuccessful result was followed by four others also ending fatally, but in 1892 Kriege[3] published a case in which recovery followed the operation. The cases which have been recorded recently are numerous and we have published several in "The Mirror of Hospital Practice.[4] Every case is of interest, and the two recorded below illustrate many points of importance. In the case at St. Thomas's Hospital the value of the saline intravenous injection containing brandy is especially noteworthy. Recent papers of value on the subject are those by Pearce Gould,[5] by Barling,[6] and by Weir and Foote.[7] For the notes of the following case we are indebted to Dr. C. R. Box and Mr. Cuthbert S. Wallace.

A woman, aged thirty-three years, was admitted into St. Thomas's Hospital on Dec. 6th, 1897. The family history was unimportant. When she was fifteen years of age she first began to suffer from abdominal pain with occasional vomiting. The vomit had once the appearance of coffee; the pains at first appeared to have no definite relation to the ingestion of food or to exercise. The patient was in service and was believed to have strained herself in making a bed. From this time onward she was unable to eat meat, since it induced pain and vomiting. She had lived on milk, gruel, and fish, but the latter at times also disagreed. Five years before admission she was treated for anæmia and three years later she had hæmatemesis which succeeded an attack of vomiting. Soon after this another profuse hæmorrhage from the stomach took place. For fifteen months prior to admission to hospital she had been treated as an out-patient for gastric ulcer. The pain latterly had become more severe. Whilst walking back from her work at about 5.45 P.M. on Dec. 6th she was suddenly seized with a sharp pain in the left side just below the ribs. She reeled and would have fallen had not her sister, who was walking with her, caught her. She was carried into a shop, where she waited until a cab was procured and she was then taken to the hospital. On the way she vomited some brownish matter which was described as having the appearance of cocoa. During the day she had taken—at 7.45 A.M., bread and butter for breakfast; at midday, bovril; and at 4.15 P.M., cocoa and a biscuit. When seen at 7 P.M. the patient had an anxious expression and was complaining of intense pain in the epigastric and left hypochondriac regions. She lay on her back, with the abdomen rigid but not distended. Percussion showed a normal area of liver dulness and no indication of any fluid in the flanks. The epigastric and left hypochondriac regions were acutely tender to the touch. The extremities were cold and the temperature in the axilla was 95·6° F. The pulse was 88, small and compressible. There was no further vomiting. The urine was acid and of specific gravity 1026; it reduced Fehling's solution rapidly. At 10 P.M. the abdomen was opened in the mid-line above the umbilicus. As shock was evidently great the median basilic vein was opened and three pints of normal saline fluid containing one and a half ounces of brandy were infused. The appearance of the patient and the character of the pulse at once improved so that both were much better at the close of the operation than at the commencement. Immediately the peritoneum was opened several ounces of milky fluid escaped. The ulcer was found on the anterior surface of the stomach quite close to the lesser curvature and to the pylorus. Though somewhat deep in the abdomen it could be dragged down under the wound. The perforation was about half an inch in diameter and was surrounded on all sides by a ring of thickening. The induration was of such extent that excision was out of the question. The ulcer was therefore inverted with a double row of Lembert's sutures and was closed by an omental graft. The intestines were then turned out on to the surface of the abdomen and were washed with sterile water; the abdominal cavity and the pelvis were carefully cleaned with sponges. The pelvis contained stomach contents, but there was no sign of peritonitis. A drain having been introduced through an incision below the umbilicus the operation wound was closed. For fifteen days after the operation the patient was fed by the rectum; but then food in gradually increasing quantities was given by the mouth. The condition of the abdomen never gave cause for anxiety. For a few days after the resumption of solid food abdominal pain was present, but thenceforward the recovery was uneventful. The reducing agent was never present in the urine after the operation. The patient was discharged from the hospital on Feb. 24th, 1898, and is now in the best of health.

SOUTHPORT INFIRMARY.

A CASE OF PERFORATED GASTRIC ULCER; OPERATION; RECOVERY.

(Under the care of Mr. G. REINHARDT ANDERSON.)

A YOUNG woman, who was apparently in good health, consulted Mr. Reinhardt Anderson on Feb. 18th, 1897, complaining of pain after food. The pain was not constant and was not accompanied by vomiting. She had vomited after every meal on the 16th, but this she attributed to a bilious attack. She had never vomited blood. The pain had, she stated, existed off and on for some months. Mr. Anderson subsequently ascertained that twelve months previously—viz., in the early part of 1896—she was a ward maid in the infirmary, but she had to give up her situation because of anæmia and persistent dyspepsia. On examination the patient was found to be somewhat anæmic with pain and local tenderness in the epigastrium. Mr. Anderson prescribed a milk diet and the usual remedies. On the 21st, at 5 P.M., he received a call to see her as it was thought that she was dying. On his arrival he found that she was in a state of profound collapse; there was profuse perspiration, the face was ashen, and she had a rapid thready pulse. She complained of severe abdominal pain. There had been no

vomiting. It seemed that after eating a very hearty meal at 1 P.M., consisting of calf's heart, peas, potatoes, and pastry, she had taken a walk of over three miles. When nearing home at 4.45 P.M. she was suddenly seized with such severe pain in the abdomen that it was necessary to put her in a cab to get her home, though it was only three or four hundred yards away. From this history Mr. Anderson suspected perforation of a gastric ulcer and on examining the abdomen he made out the following facts. The abdominal walls were rigid, hardly moving at all with respiration; there was marked tympanitic resonance with absence of the liver dulness to the upper border of the seventh rib, and there was shifting dulness in either flank to a small extent. Palpation elicited general acute tenderness. A small injection of morphia was given and arrangements were made for her immediate removal to the infirmary, which was over a mile distant. At 7.30 P.M (two and three-quarter hours after the onset of the pain) Mr. Anderson operated. The abdomen was opened by a mesial incision 5½ in. in length extending from just below the xiphoid cartilage to within an inch of the umbilicus. On entering the peritoneal cavity there was an escape of gas and turbid serum with a marked gastric odour. Flakes of lymph were already visible on the surface of the liver and the omentum as they presented in the wound. On drawing down the stomach there readily came into view a small punched-out perforation from which escaped plentifully the dark-brown fluid contents of the stomach, these at first rushing unavoidably into the peritoneal cavity. Traction on the stomach induced retching and increased the flow. The perforation was now surrounded by sponges and the contents of the stomach emptied as much as was possible into a porringer. The perforation was then secured by three rows of Lembert sutures, infolding the stomach on itself, in its long axis. Fine silk was used. The peritoneal cavity was flushed out by large quantities of sterilised water poured into the abdomen from a jug, and also by means of a glass tube; the peritoneum above and below the liver, in either flank, and in the pelvis, was thoroughly irrigated. This proceeding was continued till the fluid escaped quite clear and free from all gastric odour. Very few solid particles came into view. After systematic sponging the abdominal wound was secured in the usual way. No drain was used. The operation lasted one hour and twenty minutes and the patient bore it well. The subsequent progress was an almost uninterrupted one towards recovery. Vomiting was troublesome for the first forty-eight hours, but was relieved by sips of very hot water and powders of carbonate of bismuth. A slight attack of pleurisy with effusion on the left side appeared on the fourth day, but this gradually and completely cleared up without aspiration. Rectal feeding was maintained till the ninth day after the operation in view of the tendency of the patient to vomit and also because her general condition kept so good as not urgently to demand food by the mouth. Fish was given on the seventeenth day and chicken on the twenty-seventh day. The stitches were all removed on the ninth day, the wound soundly healed, and there was neither abdominal pain nor tenderness. The temperature, which had never been higher than 102° F. on the second day after the operation, became normal on the thirteenth day and remained so. The patient was allowed up for the first time on March 24th and was discharged on April 29th. Eight months after the operation she travelled from Holyhead to Dublin. She was very sick, but sustained no harm, and in April, 1898, she was in perfect health and free from all dyspeptic symptoms.

Remarks by Mr. REINHARDT ANDERSON.—In submitting the notes of this case I am aware that there is nothing very unusual to comment upon. I was fortunately able to see the patient within fifteen minutes of the perforation and I believe that the happy result was largely due to the very short time which elapsed between the occurrence of the accident and the opening of the peritoneum. I may also mention that the perforation was small, not larger than a crow quill, and was situated on the anterior surface near the cardiac end, and though the stomach was loaded with partially digested food not much had had time to escape into the body cavity. Moreover, I was not hampered by those difficulties which have beset many other operators when dealing with similar cases—viz., the presence of induration around the seat of the ulcer or of extensive adhesions.

The chief interest in the above case seems to me to lie in the absence of previous symptoms pointing to a gastric ulcer. The patient's complaint was of vague pain and discomfort after food, her appearance was that of good health, and she was able to fulfil without trouble the arduous duties of waitress in a busy restaurant, so that I must confess that at my first and only interview with the patient 3 days before the occurrence of the acute mischief I was not impressed with the idea that she had a gastric ulcer. I prescribed the milk diet more as a precautionary measure, advice which was evidently totally disregarded. The presence of small, solitary, punched-out ulcers, which in recorded cases are found so frequently in sudden perforation of the stomach, is a matter of some interest, for they may exist without giving rise to more than ill-defined symptoms of dyspepsia, and they may easily be overlooked without careful palpation for a tender or painful area. It is certain that since my experience in the above case I have treated with more respect similar cases coming under my care, and I have enforced the absolute rest which is needful to avoid a possible perforation. In the treatment of this accident there is little doubt that the best chance for the patient lies in early diagnosis and prompt operation.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Intra-pleural Tension.

A MEETING of this society was held on May 10th, the President, Mr. BRYANT, being in the chair.

Dr. SAMUEL WEST read a paper on Intra-pleural Tension, of which the following is an abstract. Dr. West pointed out that the two layers of the pleura, which in health are in close contact, are subject to a constant strain which tends to pull them apart called the "intra-pleural tension," which is for all practical purposes equal in amount to the elastic contraction of the lung, but opposite in direction. The respiratory movements cause constant variations in this tension owing to the different degree to which the lungs are on the stretch in the different phases of respiration. Besides this, the air is somewhat hampered both on its entrance and on its exit from the air-tubes to the extent of half a millimetre of mercury on inspiration and from one and a half to two millimetres on expiration, causing a respiratory oscillation equal to about 2 in. of water. During normal quiet breathing, both on inspiration and expiration, the intra-pleural tension is negative. During forced inspiration the negative value is increased, but during forced expiration the negative value may be converted into a positive one; but as long as the two layers of the pleura are in contact this positive pressure during expiration is supported by the chest walls and does not, except theoretically, affect the pleura. Under pathological conditions, if the pleura contain air or fluid, this pressure then will affect the contents of the pleura also. The effects produced will vary according as the pleura is occupied by fluid, which is practically incompressible, or by air, which is easily compressible. The methods of estimating intra-pleural pressure are mainly two: first, measuring the elasticity of the lung, as Donders did; and, secondly, direct investigations by passing a trocar into the pleura through the chest walls. Perl's observations were referred to and various conclusions which may be drawn from them were stated with comments. When one side of the chest is opened the admission of air goes a long way to satisfy the elasticity of the lungs on both sides. Where the two layers of the pleura are more or less adherent the intra-pleural tension is more or less diminished. Where the pleural cavity is obliterated and the one lung contracted while the other has become enlarged the elasticity of the sound lung is greatly increased, proving that this is a condition of complementary hypertrophy, and not, as it is often called, complementary emphysema. Arguments were adduced to show that the contractility of the lung was probably not purely elastic, but partly muscular, and that there was such a thing as "pulmonary tone," in the same sense as physicians speak of "vascular tone," which may vary considerably in different constitutional conditions or in different nutritive states of the lung. Under pathological conditions the two layers of the pleura may be separated either by air or by fluid, and these present each of them its own peculiarities; thus

fluid has weight, but is practically incompressible; while air is compressible, but its weight may be disregarded. In the case of fluid effusion, therefore, the height of the column above the point of the trocar would affect the manometer reading. With a small punctured wound, as with a stab, or when the lung is injured, as with a fractured rib, the air does not often enter the pleura, but passes across it and makes its way to the subcutaneous tissue. Where there is a large opening through the chest-walls at least as large as the cross-section of the trachea air will pass in and out easily during respiration, and no effect being produced upon the lung it will collapse by virtue of its own elasticity, yet not completely. On the contrary, in such cases the lung is not infrequently found considerably expanded and quite near to the chest-walls, especially if there be forced expiratory efforts, as in coughing. Where the opening in the chest walls is not large enough to allow the air to pass freely out during expiration the pressure within the pleura will rise during expiration and tend therefore to compress the lung; and this is almost always the case where the perforation of the pleura is from within—e.g., from the lung—for it can rarely happen that the air can pass as easily out through the opening in the lung during expiration as it passes in during inspiration. The intra-pleural pressure in cases of pneumothorax during inspiration and during expiration must be considered separately. (1) During inspiration the air will enter the pleura as long as the pressure within the pleura is below that of the atmosphere and then no more can enter. The inspiratory pressure, therefore, cannot exceed that of the atmosphere with air alone, or very slightly where there has been deep inspiratory effort. If the inspiratory pressure is permanently raised some other factor is necessary to produce it, and that is generally the presence of effusion. (2) The expiratory pressure in pneumothorax is always positive and may be high if the expiration be forcible. Thus considerable pressure will be exercised upon the lung and mediastinum, so that the lung will be compressed and the mediastinum considerably displaced. The respiratory oscillation in pneumothorax is generally small, for on the affected side the chest is usually in the position of maximum inspiratory expansion, and on the opposite side, owing to the displacement of the mediastinum, the expiratory contraction of the lung is diminished. The observations upon which the preceding remarks were founded consisted of 20 paracenteses performed in 11 cases of pneumothorax. In 2 cases the inspiratory pressure was zero, but in the rest it was positive, and all of those associated with fluid, the range of pressure thus varying from zero to 9 in. That the pressure in pneumothorax when fluid is present is not higher than it is must be due to the fact that a large amount of the air is absorbed. A persistently high pressure would probably indicate some diseased condition of the pleura and lung which has prevented the ordinary absorption of the air. In serous effusion the pleura, it is probable, is kept dry in health by the action of what has been described as the "lymphatic pump"—viz., the stomata—and the valved lymphatics into which they lead, worked by the respiratory movements. Fluid, therefore, may accumulate in the pleura in two ways; either it may be poured out in larger quantities than the pump can remove or the amount of fluid may not be above the normal, but the pump defective. When fluid collects in the pleura it falls by its own weight to the lower part, and it is the lower parts of the lung consequently that become more collapsed, but the tension in the upper part is also reduced, as is shown by experiment. In estimating the intra-pleural pressure with serous effusion something will depend upon the seat of puncture and allowance has to be made, if possible, for the height of the column of fluid above the mouth of the trocar. The observations upon the pressures in pleural effusion were then recorded. The records show that with serous effusion the pressures vary greatly and irregularly; that there is no definite relation between the size of the effusion and the amount of pressure, for there are instances of large effusion with low or even negative pressure and of small effusions with high pressure. The respiratory oscillation is generally reduced and may be completely absent. Inasmuch as the action of the lymphatic pump depends upon the respiratory movements, of which the respiratory oscillation is the index, it is evident that where the respiratory oscillation is absent the mechanism for the removal of fluid is at a standstill. Where the respiratory oscillation has been absent at the commencement of paracentesis it often returns at the end, showing that the lymphatic pump has been set to work once more. This explains why the removal of a small amount of fluid often determines the rapid disappearance of the rest. The observations recorded show that intra-pleural pressure in serous effusion is not so simple as it might *a priori* be thought to be; that it depends upon many factors which are difficult to allow for; and that the whole subject requires further investigation. Intra-pleural pressure in empyema is much simpler than in serous effusion. In all the cases observed the pressure was considerably increased, the lowest being + 3 and the highest + 16; but, as might be expected, small effusions are quite as likely to have high pressures as large. The respiratory oscillation is practically absent. The bearing of these various facts upon practice was referred to in the course of the paper.

Dr. LAZARUS-BARLOW said that there were several points on which he would like to offer some criticisms. Dr. West had explained the increase of elasticity on the sound side as proving that the lung was in a condition of compensatory hypertrophy, but apart from the improbability of true hypertrophy occurring in so complicated an organ as the lung the increase might be partly due to resilience of the chest wall, which Sir R. Douglas Powell had shown to be an important factor in the causation of emphysema. In any distended elastic bag the recoil was very much greater with considerable amounts of distension than when it was only slightly distended. As to the existence of "pulmonary tone" he had been working at the histology of the lung and had been unable to find any unstriped muscle fibres in the lung, although there were some in the lung of the guinea pig. There were, of course, fibres in the blood-vessels, but the investigations of Bradford and Dean had shown that the nerves had little influence over them. As regards the "valve theory" accounting for the increase of pressure in some cases of pneumothorax he thought that the condition of the pleura must be taken into account as well. Cohnheim had shown that it was impossible when the pleura was healthy to obtain sustained increase of pressure owing to the rapid absorption. Hence cases of pneumothorax occurred particularly in cases of tuberculosis where the pleura was abnormal. Dr. West attributed the rapid absorption of fluid after a small portion had been drawn off to the action of the lymphatics, but Dr. Lazarus-Barlow thought that the experiments of Dr. Starling showed that fluids injected into a serous cavity were absorbed chiefly through the vessels. If a coloured solution, for instance, were injected the colouring solution appeared in the urine before it appeared in the thoracic duct. He thought that it was probable that this absorption depended, not only on local conditions in the thorax, but on some alteration of balance throughout the body.

Dr. NORMAN MOORE said that the paper would be useful in directing attention to the question of entrance and exit in the case of the pleura. It was now recognised that a serous pleural effusion did not necessarily become purulent in time, but that the entrance of some organisms was necessary. Some went so far as to say that there was also some tuberculous disease of the pleura, but without going to that extreme Dr. Moore considered that this was more frequent than had been previously supposed. The tuberculosis might remain localised to the pleura, just as it often did in the case of the peritoneum.

Dr. CALVERT said that he had made experimental observations on the injection of a small quantity of fluid into the lower part of the pleural cavity. He found that there was not merely compression of the base, but that there was a general contraction of the lung which affected the apex as soon as the base. He did not agree that it was necessary for the lung to have collapsed before there could be positive pressure. He thought that this positive pressure occurred when the effusion was localised by adhesions.

Dr. ROSE BRADFORD agreed with Dr. Calvert as to the increase of pressure in cases of localised effusions and remarked that the physical signs in such cases resembled those of empyema rather than those of free pleural effusion, particularly in the presence of tubular breathing. He agreed with Dr. Lazarus-Barlow that the absorption from serous cavities was mostly by way of the blood-vessels. But as to the existence of pulmonary tone, he pointed out that his experiments showed not that the nerves had no influence on the pulmonary vessels, but that it was insignificant compared with the vaso-motor arrangements of the systemic

vessels, so that the existence of such a tone as Dr. West had described was possible. The pulmonary vessels had great power of absorption and this was greatly favoured by the movements of the lungs. The collapse of the lung in cases of pneumothorax was partly due to the rapid absorption of the air in it by its own blood-vessels. The valve theory he considered hypothetical.

Mr. PEARCE GOULD asked for an explanation of the displacement of the heart and mediastinum in cases of pleural effusion. The presence of a small quantity of fluid had been mentioned as necessary for increase of intra-pleural pressure in cases of pneumothorax. He mentioned a case of a boy admitted to hospital with pneumothorax due to injury of the chest, from whose chest air escaped with a rush on paracentesis, but in whom there were no signs of any fluid in the pleural cavity.

Dr. WEST, in reply, said that he did not think that it was any more difficult to conceive of pulmonary hypertrophy than of hypertrophy of the kidney which was so common. He was aware of Cohnheim's experiments on dogs, but it did not follow that the same conditions obtained in man. Several speakers had spoken of the absorption of serous fluid through the vessels, but he thought that the lymphatics also played an important part.

MEDICAL SOCIETY OF LONDON.

Treatment of Tuberculous Disease of the Bladder.—Recurrent Hæmatemesis due to Hepatoptosis.

A MEETING of this society was held on May 9th, the President, Dr. SANSOM, being in the chair.

Mr. MANSELL MOULLIN read a paper on the Treatment of Tuberculous Disease of the Bladder. He called attention to the present very unsatisfactory methods of treating tuberculous cystitis. If constitutional methods failed or were impracticable from a patient's position in life or from other reasons there was nothing left. Local applications were condemned on various grounds. They increased the risk of septic cystitis. They helped to extend the tuberculous disease by the way in which they bruised and injured the still healthy portion of the mucous membrane; and they were of no use, for they never reached their mark. The bacilli were much too well protected by the depth at which they lay in the tissues and the coating of caseous *débris* that formed upon the floor of the ulcers to be affected by iodoform or lactic acid or any other substance that could be injected into the bladder. Drainage at best was only a palliative and in many cases made matters worse, as the tuberculous disease grew down and infected the track of the drainage-tube. For cases such as these if constitutional measures failed there was nothing left, and the question Mr. Mansell Moullin wished to raise was whether some might not be relieved, and perhaps even cured, by adopting much more energetic measures at a much earlier date; whether, in short, the local treatment of tuberculous cystitis had not fallen into its present state of disrepute because it had been too feeble and too late. Suprapubic cystotomy was an operation almost devoid of risk, at any rate in the earlier stages of tuberculous cystitis. Removal of the growth either by excision or erasion under such conditions was a perfectly feasible measure whatever it might be later. The only argument against operation was that the disease in the bladder was nearly always secondary and therefore its removal would not really benefit the case. Mr. Mansell Moullin pointed out that the mucous membrane of the bladder rarely became infected through the epithelial surface. This, unless it was injured in some way, was an efficient protection. Nearly always the bacilli invaded it either by direct continuity from some neighbouring organ or through the medium of the blood-vessels or the lymphatics. In the case of tuberculous pyelitis this was undoubtedly easy as there was a free communication between the lymphatics of the pelvis of the kidney and those of the mucous membrane of the bladder, and when the ulceration began at or around the orifice of one of the ureters the presumption was in favour of its being secondary. But when the disease commenced in other parts of the bladder, or even of the trigone, this was by no means so certain. Tuberculous disease usually began in the trigone of the bladder, not because this was in relation with the generative organs, but because this was the most vascular and physiologically the most active part of the bladder. The bacilli infected it first for the same reason that they attacked the growing epiphyseal line of a bone and not the shaft; and, further, the communication between the lymphatics of the genital organs and those of the mucous membrane of the bladder is by no means free. Especially in the case of women, whose generative organs were not so prone to tuberculous disease as those of men, the tuberculous cystitis, if not secondary to pyelitis, was nearly certain to be primary; and even in men, judging from the extreme frequency of tuberculous epididymitis and the comparative rarity of tuberculous cystitis, the extension of the disease from one to the other would not be so easy as it was usually imagined. Everything depended upon early diagnosis and now that the cystoscope and centrifugalisation of the urine were in common use there ought to be no difficulty in diagnosing the beginning of tuberculous cystitis and eradicating it thoroughly. Mr. Mansell Moullin brought forward particulars of various cases in support of this view. He had operated three times himself and seen two other cases in which operation might have been performed with advantage. One patient was operated upon in January, 1891, and was still well. Two others had been operated upon by Mr. Battle, one, the first in England, so long ago as 1889. Five years afterwards the patient had had no recurrence. And there were upwards of 30 cases recorded as having been operated upon abroad. In most of these the disease was primary, but in 3, other organs were involved as well and yet the patients had been benefited very materially. Reverdin's patient, for example, had suffered two years before from tuberculous epididymitis and was well two years after the operation in spite of having had a perinephritic abscess; Greiffenhagen's patient had a caseous abscess in the perineum, probably in connexion with one of the vesiculæ seminales; and Bell has reported a third case in which, in spite of the presence of tuberculous epididymitis, the bladder symptoms almost disappeared after the ulcers had been scraped with a Volkmann's spoon and cauterised. Two years later, when the testis was removed, the man was described as well with the exception of some incontinence of urine. Mr. Mansell Moullin agreed that it was of no use attempting a radical cure when the bladder had become so rigid and contracted that suprapubic cystotomy was almost out of the question. But he urged that if the diagnosis was made at the beginning, as it should be, and the patient did not rapidly improve under constitutional measures, suprapubic cystotomy followed by excision or erasion of the growth offered a fair prospect of cure in cases in which the infection of the bladder was primary, and that even in those cases in which other organs were involved as well the operation would, with very little risk to life, provide a means by which much of the suffering which inevitably follows in those cases might be successfully prevented.—Mr. FREYER observed that there were great difficulties in the diagnosis of tuberculous disease of the bladder. The hæmaturia, pain, and increased frequency of micturition which were usually present often suggested the presence of a stone, but, whereas the increased frequency of micturition in the case of calculus diminished when the patient was recumbent and during the night, there was no such remission in the case of tuberculous cystitis. Primary tuberculous disease of the bladder was very rare. He thought that it was almost always secondary to tuberculous disease in some other part of the genito-urinary tract, the site of primary disease being, in order of frequency, (1) epididymis, (2) vesiculæ seminales, (3) prostate gland, (4) testicle, and (5) kidney. He himself had opened the bladder in six cases for tuberculous cystitis and he had regretted it in every case but one, and he thought that constitutional medical treatment did more for the patient. The local mischief appeared to increase after the erasion and months elapsed before the suprapubic incision could be closed. He could not agree that the operation was free from risk seeing that Mr. Barling had shown that out of about 50 children on whom suprabubic cystotomy was performed for stone no fewer than 20 per cent. succumbed. As regards the site of the disease he thought from cystoscopic examination that most of the lesions were at the neck of the bladder or at the trigone owing to the proximity of the vesiculæ seminales, &c.—Mr. BATTLE observed that it was worth while trying to give surgical relief to these cases as the state of the patient was such an extremely miserable one. There were two classes of cases, the first in which there was a definite ulcer which might be easy to reach and a second in which the mucous membrane was

studded all over with tuberculous granulations, these being most numerous at the trigone. He agreed that primary cases were very rare, but when they occurred they were very amenable to surgical treatment if they were attacked early. He mentioned five cases in which he had operated for tuberculous cystitis, one in a woman, the other four in men. 1. A woman, thirty years of age, who was extremely exhausted from chronic cystitis. She improved very much after scraping, but died from hemiplegia due to cerebral thrombosis. 2. A man who got well and continued well five years after operation. 3. Another who refused to continue treatment after the operation and yet was free from sign of tubercle elsewhere and the local condition had greatly improved. 4. A patient who had had hæmaturia for four months. The mucous membrane was found covered with granulations which were scraped away, but he did not improve much, although the suprapubic opening was kept open for six weeks. 5. A man in whom no improvement occurred. He had not seen the evil results from suprapubic cystotomy which had been referred to unless an attempt were made to close the wound too early.—Dr. CLIFFORD BEALE said that the statistics of the Victoria Park Hospital for Diseases of the Chest showed how rare was the association of tuberculous vesical disease with that of the lungs. Dr. Beale mentioned one obscure case in which there was much pain, with intermittent escape of pus in the urine, which relieved the pain. At the necropsy this was found to be due to tuberculous disease of the vesiculæ seminales.—Mr. MANSELL MOULLIN, in reply, said that he did not claim that every case could be benefited by cystotomy. He was surprised to hear it said that cystitis was so often secondary to tuberculous vesicular disease. It occurred in women in a large proportion of cases, and here this explanation could not hold good. Even if the primary disease were in the genito-urinary tract all parts of it, including the seminal vesicles, could now be easily reached by operation.

Dr. MACNAUGHTON-JONES read a paper on Recurrent Hæmatemesis due to Complete Hepatoptosis discovered by Laparotomy. The patient, aged thirty-eight years, the mother of seven children, had been very delicate in childhood and had suffered from severe gastrodynia, with vomiting, amenorrhœa, and anæmia during puberty. At the age of nineteen years there was hæmatemesis, supposed to be due to either gastric ulcer or vicarious menstruation. She was married at the age of twenty-three years and five months after her first labour there was recurrence of the hæmatemesis. Following a miscarriage in 1895 there was severe metrorrhagia and in December of the same year there was again hæmatemesis. The metrorrhagia recurred in 1896, when she had an attack of typhlitis. In 1897 gastrodynia and vomiting occurred after eating some shellfish and continued on and off until July, when severe hæmatemesis again set in. On July 14th she was seen with Dr. William Barter. She then was blanched, extremely weak, with rapid pulse, nourishment being administered by enemata, as no food could be retained by the stomach. There was no pain. The abdominal percussion note was resonant in every direction save in the right hypochondriac, lumbar, and inguinal regions, in which a fairly large moveable mass extending from the lower ribs to the inguinal region could be defined. Its edge gave the tactile impression usually experienced on feeling an enlarged spleen. There was neither a renal nor hepatic line of demarcation. Diagnosis resolved itself into the question of hepatic or renal enlargement and the view was taken that it was an enlarged and moveable renal tumour. The condition of the patient was most alarming and precluded abdominal section. Her condition having improved abdominal exploration was carried out on September 17th in the presence of Mr. Bland Sutton. The tumour was reached by the ordinary Langenbuch's incision for nephrectomy, but when the abdominal cavity was opened it was found that it was the edge of the liver which extended from the costal cartilages to the iliac fossa, the right lobe being in the latter position. The gall-bladder was exposed and was found a few inches below and to the right of its natural position. On passing the hand under the diaphragm the vault was found to be empty. The liver was darker than usual and the surface was somewhat deeply injected. The spleen and both kidneys were examined and found to be normal. The liver was resting directly on the right kidney. It was replaced in the same position and the stomach was taken out, laid on the abdominal wall, and in its turn closely examined. It was somewhat enlarged and its vessels were rather distended, but nothing abnormal to touch was found. After careful readjustment of the parts the abdominal wound was closed in the usual manner. The patient made an uninterrupted recovery without any complication. There was no sickness after the operation nor has there been any since. She gradually returned to ordinary diet and left on Oct. 10th for the seaside. "Since then," Dr. Barter writes, "the patient has gone on improving and now, with the help of an abdominal support and with due regard to careful dieting and exercise, is better than she has been for years." Dr. Macnaughton-Jones reviewed the literature of displacements of the liver hitherto published, quoting Mariano Semmola's and Giofredi's exhaustive paper on the subject in 1895, and the condition "hepatoptosis," or migratory or moveable liver, the term applied by Glenard to this condition, in contra-distinction to transposition of the liver, of which but a few cases have been recorded. In 1754 Laurent Hiester demonstrated a laterally displaced liver on the cadaver and Catani in 1866 for the first time on the living subject. In the majority of cases only a lobe has been displaced. No such complete displacement as occurred in this case had, so far as he was aware, been described or discovered during life by operation. Out of 70 cases which had been collected up to 1895 by Graham, in only 8 was there any certainty of diagnosis, and in but 4 was the condition discovered by operation. Peters, Richelot, Terrier and Baudain, and Binnie were the operators. Billroth first sutured the lobe of the liver to the abdominal wall and h patopexy had been successfully performed by Marchand and Ischering and other operators. The particulars of these cases and of others were given where the liver was found in an umbilical or abdominal hernia. The association of hepatoptosis with moveable and enlarged kidney was frequent, hence the error into which some had fallen of mistaking the hepatic tumour for a renal one. The assigned causes, as congenital malposition, enlargement of the kidney, injuries, tight lacing, and lengthy ligaments, were considered, and the more common symptoms to which hepatoptosis gave rise. In many cases hepatopexy was out of the question, as in the case brought forward, but its feasibility had been proved in the instance of partial lobular displacements.—Mr. BATTLE said that during the last few weeks he had met with a case which he thought to be of the same nature. The patient came to him on account of severe right-sided abdominal pain. She was forty-five years of age and had a lax, pendulous abdomen. A mass, believed to be the liver, was felt lying transversely just below the umbilicus. When the patient stood up the mass sank down to the level of Poupart's ligament. The application of a flannel bandage had entirely relieved her symptoms.—The PRESIDENT said that the association of hæmatemesis with hepatoptosis was a very unusual one. It was curious that although there was so much dislocation of the organ and interference with the position of the vessels ascites had been present in so few of the recorded cases.—Dr. MACNAUGHTON-JONES, in reply, said that the mass exactly simulated a renal tumour and was only discovered to be the liver at the operation. In another case its nature might be suspected if there were absence of the hepatic dulness in its normal position.

The following is the list of officers elected for the ensuing year:—President: Mr. Edmund Owen. Vice-Presidents: Dr. J. Kingston Fowler, Mr. John H. Morgan, Dr. J. Mitchell Bruce, and Mr. George R. Turner. Treasurer: Mr. David H. Goodsall. Librarian: Dr. William Henry Allchin. Honorary secretaries: Mr. William H. Battle and Dr. James Calvert. Honorary secretary for foreign correspondence: Mr. Alban H. G. Doran. Council: Dr. John Anderson, C.I.E., Mr. William H. Baker, Dr. E. Clifford Beale, Dr. Frederick L. Benham, Dr. Robert L. Bowles, Mr. Stanley Boyd, Dr. William Ewart, Mr. A. Pearce Gould, Dr. Constantine Holman, Dr. Hector W. G. Mackenzie, Dr. Robert Maguire, Dr. Sidney H. C. Martin, F.R.S., Dr. J. Baldwin Nias, Dr. Humphry D. Rolleston, Dr. Amand Routh, Dr. A. Ernest Sansom, Mr. Morton Smale, Dr. John C. Thorowgood, Mr. Frederick C. Wallis, and Mr. Arthur K. Willis.

OBSTETRICAL SOCIETY OF LONDON.

Primary Carcinoma of the Fallopian Tube.—Exhibition of Specimens.

A MEETING of this society was held on May 4th, Dr. C. J. CULLINGWORTH, President, being in the chair.

Dr. HUBERT ROBERTS read a paper on a case of Primary

Carcinoma of the Fallopian Tube. The patient, a woman, aged forty-three years, had been married seven years, but had not been pregnant. She had been in good health until March, 1896, when she had a violent attack of abdominal pain accompanied by a vaginal discharge. Other similar attacks occurred in July and November and gushes of watery fluid were noted. On admission in February, 1897, the patient was thin and the uterus was displaced to the left side by a fixed mass of the size of a hen's egg felt in the right fornix, but not tender. There was a watery vaginal discharge. The right tube, enlarged to the size of a Bologna sausage, was removed by Mr. Meredith on Feb. 24th, 1897. It was full of papillomatous-looking growth, which microscopic sections showed to be carcinoma. Reference was made to published cases of primary carcinoma of the Fallopian tube. Removal was advocated, the prognosis being by no means gloomy.

Mr. ALBAN DORAN gave a short history of the literature of Primary Carcinoma of the Fallopian tube with a table of the 23 cases published up till April, 1898, to which he now added a twenty-fourth case reported by Jacobson in *La Gynécologie* for April, 1898; the tube was removed through a vaginal incision and, as in other reported cases, the uterine end was free from disease. The patient was sterile and it was interesting to note that out of the 24 cases only 3 had borne so many as 3 children. Mr. Doran had recently operated on a woman, aged forty-five years, who had been twelve times pregnant. On March 13th she had an attack of labour-like pains, a similar seizure occurring two days later; with each pain much water escaped, till at length she was drenched as in an ordinary labour. A large tender mass could be felt in the right fornix and a smaller body on the opposite side. The symptoms suggested papilloma or cancer of the tube, but he simply found tough, tortuous tubes, with their canals undilated, closely adherent to the uterus and adjacent structures. Mr. Doran believed that primary cancer was commoner than papilloma of the tube or that the latter was very liable to malignant degeneration. Of 7 authentic cases of papilloma 2 had died from the operation, whilst one (Watkins, New York) was very recent; Kaltenbach's case (No. 3 in the tables) had proved malignant, whilst the earliest of all the papilloma series (Spencer Wells 1879) was alive and in excellent health in 1897, though the clinical symptoms before operation were very grave. He agreed with Dr. Stevens that cancer of the tube might arise from Wolffian tubes included in the tubal wall (von Recklinghausen). In order to gain as precise knowledge as possible about recurrence Mr. Doran had communicated with all the authors of cases where the report was incomplete. As for surgery, removal of the tube alone through the vagina seemed questionable, as the state of surrounding parts could not readily be ascertained. Watkins and Schanta removed the uterus with the cancerous appendages. This operation is questionable, however, when the uterine end of the tube is free from disease and useless when the outer end has infected structures to which it has become adherent.

Dr. PETER HORROCKS pointed out that carcinoma of the cervix was common and nearly always occurred in parous women; carcinoma of the body of the uterus was much rarer and occurred chiefly in multiparæ; whilst carcinoma of the Fallopian tubes was the rarest of all and occurred in sterile women chiefly. He thought that clinical evidence showed that tissues which were used much and were liable to damage were more prone to carcinoma than others and this rather favoured the idea that carcinoma was due to, or in some way associated with, a microbe which would first meet with the cervix, and if that were damaged (split cervix) elect the damaged part for its growth. But if it were a multiparous cervix then the microbe might travel into the body or Fallopian tube. It was better to remove this growth in the tube by abdominal than by vaginal section.

Dr. AMAND ROUTH alluded to the difficulty of diagnosis. In Case 2 in Mr. Doran's table, which had occurred in his own practice and in the majority of those in the table, there was usually early continuous pelvic pain simulating acute salpingitis with slight perimetric extension; and when this was associated with sanious, often offensive, discharge, together with a tubal swelling, the diagnosis of some new growth in the tube was probable and fairly certain if by a preliminary dilatation the uterus could be excluded as the source of the discharge.

Dr. ADDINSELL drew attention to the fact that in nearly all the recorded cases the most noticeable clinical features were pain and watery discharge and pointed out that the presence of these symptoms could not be considered pathognomonic of either primary carcinoma or papilloma of the tube as they occurred in some cases of hydrosalpinx.

Dr. GILES drew attention to the unfavourable prognosis in cases of cancer of the Fallopian tube. Of the 23 cases in Mr. Doran's table, in 2 no operation was performed or it was incomplete; in 2 which recovered the patient was lost sight of; in 2 the operation was fatal; of the remaining 17 cases recurrence took place in 10, the time of recurrence averaging from six to eight months after operation; of the 7 cases reported as remaining well there was only 1 that could be safely pronounced to be cured (seven years after operation). In the others the time was too short to allow of a positive statement, the longest time being nineteen months.

Dr. ROBERTS and Mr. DORAN replied.

The following specimens were exhibited:—

Mr. TARGETT: Intestinal Obstruction following Ovariotomy.

Dr. PETER HORROCKS: Fibroma of the Uterus with Sarcomatous Degeneration.

Mr. ALBAN DORAN: Hæmorrhage from the Fallopian Tube without evidence of Tubal Gestation.

OPHTHALMOLOGICAL SOCIETY.

Chip of Steel in the Eye with Skiagraph.—Ophthalmoplegia Externa with Impairment of the Orbicularis Oculi.—Rudimentary Development of the Iris.—Conical Cornea Treated by the Galvano cautery.—Case of Retinitis Circinata.—Peculiar Condition of the Lens.—Exhibition of Specimens.

A CLINICAL meeting of this society was held on May 5th, the President, Mr. H. R. SWANZY, being in the chair.

Mr. ERNEST CLARKE and Dr. MACKENZIE DAVIDSON showed a case of Chip of Steel in the Eye with Skiagraph. The patient was struck by a chip of steel in the right eye in November, 1897. A scar could be seen in the cornea and in the anterior and posterior portions of the lens capsule. The opacity in the lens had somewhat increased since and vision was reduced from $\frac{6}{\text{fr.}}$, when first seen, to $\frac{6}{\text{fr.}}$. A skiagraph taken by Dr. Mackenzie Davidson showed that the piece of metal was lodged in the ciliary region at the lower part. On ophthalmoscopic examination a mass of exudation could be seen at this point. The exposure had now been reduced to ninety seconds and in the case of a child to one minute.

Dr. JAMES TAYLOR showed a case of Ophthalmoplegia Externa with Impairment of the Orbicularis Oculi. Hughlings Jackson had first drawn attention to a case exhibiting weakness of the orbicularis in paralysis of the third nerve exemplifying Mendel's hypothesis that the ultimate nerve supply of the orbicularis was the third nerve. Mention was made of the similar association between paralysis of the orbicularis oris and the hypoglossal nerve.—Dr. BREVOR said that he had shown a case at this society a few years ago in which there was double ptosis and weakness of the orbicularis; it was probable that in most of the cases where the nucleus of the third nerve was involved the orbicularis was affected. Dr. Taylor's case was important as other muscles which had a nerve supply originating in the bulb—those of the palate—were affected; he believed this to be rare.—Mr. FLEMMING said that anatomists were now agreed on anatomical evidence that the orbicularis was supplied from the third nerve nucleus.

Mr. JOHN GRIFFITH showed two cases of Rudimentary Development of the Iris. The patients were brother and sister, in whom the iris was present only as a rudimentary band, which was absent in the lower outer part entirely; the choroid and ciliary body were normal. In one of the cases there were anterior polar cataracts without sign of previous perforation of the cornea and the lenses were slightly displaced upwards. In both patients there was defect of the enamel of the teeth and there was a history of fits.—Mr. SYDNEY STEPHENSON had shown at the society two brothers with daniridia in whom there was deficiency of the enamel of the teeth known to dentists as hypoplasia.

Mr. G. A. CRITCHETT showed a case of Conical Cornea treated by the Galvano-cautery. The improvement in vision had been in the right eye from $\frac{6}{60}$ to $\frac{6}{9}$ and in the left from $\frac{6}{60}$ to $\frac{6}{24}$. In the last series of cases, about 15 in number, he had tried not to perforate the cornea; he used the cautery

wire at the lowest possible red-heat, so that not much more than the epithelium was affected; the whole area intended to be affected was burnt with this, then at a slightly greater heat he burnt a smaller disc within this area; then at a higher temperature still he burnt the centre at a point only. During the first burning the aqueous disappeared and the iris came into contact with the cornea. He used a flat, medium-sized point except for the central and last burning, when he used a small one.—Mr. HARTRIDGE asked the reason for using the different degrees of heat; he was in the habit of using one temperature only and had never seen the aqueous disappear.—Mr. CRITCHETT said he thought a better cicatrix was obtained by this method.—Remarks were made by Mr. DOYNE, Dr. COLLINS, Dr. TAYLOR, Mr. GRIFFITH, and Mr. GUNN, in reply to which Mr. CRITCHETT said that although the iris in these cases was in contact with the cornea the aqueous did not completely disappear in the centre of the pupil, and mentioned one case in which perforation during the application of the cautery was followed by escape of aqueous. Tension was diminished. The cautery was applied outside and below the centre of the pupil so as not to interfere with the visual portion, the apex of the cone being also below.

Dr. FISCHER showed a case of Retinitis Circinata. The patient was a woman, aged sixty-six years, unconscious of anything wrong with her left eye. She was healthy and had no ascertainable kidney disease. The right eye was quite normal; in the left there was well-marked retinitis circinata completely surrounding the yellow spot, which was degenerated.—Mr. LAWFORD thought this case was not typical inasmuch as there was little or no change at the yellow spot and the band of exudation was distinctly raised. The other eye also was quite free from retinal disease.—Mr. GUNN thought this one of the manifestations of old-standing œdema of the retina and that it was similar in nature to the asterisk seen in renal retinitis. There were arterial changes in this case.—Mr. DOYNE thought that the exudation was decolourised blood. The greater functional activity in the muscular region explained the earlier absorption there.—Mr. HARTRIDGE had shown a case at the society some years ago; the exudation had since entirely disappeared, leaving only pigmentation.

Mr. MARCUS GUNN showed a Peculiar Condition of the Lens in a child who had a cataract in the right eye which had been diagnosed in early life, but nothing had been done for it. The right iris was much lighter in colour than the left; there was punctate deposit on the back of the cornea; the centre of the pupil was like an ordinary opaque membrane, with holes in it through which the optic disc could be seen with + 10 D. The peripheral part of the lens appeared like a brown grey granular exudation raised above the level of the central capsule. He thought this might be possibly a uniocular cataract which had undergone spontaneous shrinking, leaving organised lymph on the suspensory ligament.

The following specimens were shown:—

Mr. ROCKLIFFE: (1) Two specimens of Cystic Retina; some of the cysts were between the inner and outer nuclear layers and the others were difficult to locate owing to degeneration of the retina; and (2) specimens of Pseudo-Glioma.

Surgeon-Captain HERBERT: Specimens of Epithelial Xerosis of the Conjunctiva.

Mr. DEVEREUX MARSHALL and Mr. RIDLEY: Specimens of Persistent Hyaloid Artery with Atypical Development of the Vitreous.

Dr. G. H. HOGG: A case of Polyceria.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

Exhibition of Specimens.—Catarrh of the Antrum.—Method of Prolonging Nitrous Oxide Anæsthesia for Dental Operations.

A MEETING of this society was held on May 2nd at 40, Leicester-square, W.C., Mr. W. E. HARDING being in the chair.

The CURATOR stated that he had received Two Mandibles (human) which had been dug up near Worthing and were supposed to be about 600 years old. He also stated that Mr. Whatford had presented to the museum models of the mouth of a young woman, aged seventeen years, showing Complete Absence of the Premolars, Maxillary and Mandibular.—The CURATOR also exhibited the Skull of a Young Adult Lion showing a maxillary canine the tip of which had only erupted. An examination of the tooth showed that it was distinctly stunted, the end of the root being formed of an irregular mass of tissue, probably osteo-dentine.

Mr. W. R. ACKLAND read notes on cases of Catarrh of the Antrum and in referring to the anatomy of the antrum stated that in 12 antra which he had examined he had found the opening into the nasal fossa completely closed in 4.

The HONORARY SECRETARY read for Mr. ALFRED COLEMAN a short note on a Method of Prolonging Nitrous Oxide Anæsthesia for Dental Operations. The apparatus used consists of a hood fitted so as to cover the nostrils; to this is attached a tube which is carried over the top of the head to a bag which rests at the back of the chair, the bag in its turn being connected with bottles containing the nitrous oxide. During administration slight pressure is kept up on the bag. In 15 cases recorded by Mr. Coleman a period of anæsthesia ranging from about one to five minutes had been obtained. The patients were specially selected, care being taken to administer to only those perfectly free from any nasal obstruction.—Dr. HEWITT and Dr. SILK took part in the discussion and pointed out some of the disadvantages of the system; while Mr. PATERSON expressed the opinion that the system of prolonging the anæsthesia was a good one and would undoubtedly prove of value in practice.

HARVEIAN SOCIETY OF LONDON.

100 Operations for Stone in the Bladder.

A MEETING of this society was held on April 28th, the President, Dr. JAMES F. GOODHART, being in the chair.

Mr. P. J. FREYER read a paper entitled, "A Recent Series of 100 Operations for Stone in the Bladder, with Some Practical Remarks Thereon," which will be found on p. 1319 of our present issue.

Mr. SWINFORD EDWARDS congratulated Mr. Freyer on the brilliant results of his last series and said that he was thoroughly in accord with everything that had fallen from his lips. Mr. Edwards remarked that though in skilled hands litholapaxy was easy of performance and gave the best results he considered that for surgeons who had not some experience in the operation complicated or difficult cases would be best treated by suprapubic lithotomy. He then touched upon some of the difficulties which might arise either in sounding, crushing, or evacuation, and pointed out the means for overcoming them. Mr. Edwards mentioned that in his own last 100 cases of litholapaxy there were 5 deaths, in 4 of which the fatal termination was due to advanced renal mischief.

The PRESIDENT asked whether Mr. Freyer ever met with stones which were impossible to crush on account of their hardness. He asked for details as to the method of washing out the bladder. In experiments on the cadaver he had sometimes found great difficulty in evacuating the bladder. He congratulated Mr. Freyer on the success of his treatment.

Surgeon-Colonel CALDECOTT spoke of the success which attended litholapaxy in India as compared with the results of other operative procedures.

Mr. TEMPLE MURSELL remarked upon the rapidity with which cases of vesical calculus complicated with cystitis of long standing recovered after litholapaxy without drainage and frequently without any further washing out of the bladder. With regard to calculi which resisted crushing it was very rare to find such cases, but in the few cases that were found or where the calculus had formed around a foreign body which could not be extracted through the urethra with the lithotrite suprapubic cystotomy could readily be performed by cutting on the point of the lithotrite still holding the calculus or foreign body pressed against the anterior bladder wall.

Mr. FREYER, in reply to questions by the PRESIDENT, said (1) that amongst several hundreds of cases of stone operated on by him in the last ten years, since he had become more or less expert with the lithotrite, he had only met with one stone that was too hard to crush, though the calculi had ranged up to 6½ oz. in weight. Strange to say, this was a comparatively small urate stone of 2 oz. in a female, on which his largest lithotrite (No. 18) could make no impression. He found, contrary to what was usually taught, that certain urate

stones are more difficult to crush than oxalates. (2) That a practised hand, as a rule, found no difficulty in clearing the bladder of the last fragments with a properly constructed aspirator. Experiments on the cadaver were deceptive, as the bladder did not expand and contract as in the living subject. There was no selection of cases, these 100 being the only bladder stones that came under his care during the period over which they extended. His success was not unique, as several surgeons in India had recorded similar series of 100 litholapaxies without a death, and he might point to the excellent results from this operation in St. Peter's Hospital, where last year they had had 51 litholapaxies with only 1 death. When stricture of the urethra was complicated with perineal fistula he (Mr. Freyer) preferred as a rule external to internal urethrotomy as more likely to cure the fistulæ, but he agreed with Mr. Swinford Edwards that internal urethrotomy might sometimes be preferable, particularly when there was only a single fistula. In fact, he (Mr. Freyer) had such a case at present under his care in private practice, where the fistula had rapidly closed after internal urethrotomy. He regretted to have to differ from his friend and colleague Mr. Edwards regarding suprapubic lithotomy, which he, Mr. Freyer, considered should be had recourse to only in exceptional cases, such as a very large and hard or encysted stone. It was true that the operation was simple and the requisite instruments might be found in a pocket-case, but in its very simplicity lay one of its chief dangers, as being tempting to the young and inexperienced surgeon not provided with litholapaxy instruments. He (Mr. Freyer) maintained, however, that an operation was to be judged, not by its simplicity, but by the mortality attending it, and Mr. Barling of Birmingham had recently[1] collected statistics from twelve large hospitals in London and the provinces, from which it appeared that suprapubic lithotomy in children had been attended by the appalling mortality of about 20 per cent., whereas lateral lithotomy and litholapaxy were attended by a mortality of less than 5 per cent.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Operation versus Taxis in Strangulated Hernia.—Surgical Treatment of Paralysis.

A MEETING of this society was held on May 6th, Dr. H. P. POTTER, President, being in the chair.

Mr. MCADAM ECCLES read a paper on Operation *versus* Taxis in Strangulated Hernia. By strangulated hernia he understood a hernia which contained bowel, the lumen of which was obstructed by pressure from without, either partially or completely, and at the same time this pressure caused an interference with the circulation through the vessels of the intestinal wall. Two lines of treatment offer themselves in such a condition, taxis or operation, either undertaken to procure the reduction of the gut with as little delay as possible. Against the employment of taxis, he said, might be urged the following facts:—1. Taxis may bruise, lacerate, or even rupture the bowel. 2. Taxis does not permit of a view of the intestine before reduction. 3 Taxis involves the return of fluid from the sac as well as the bowel, which fluid may be septic. 4. Taxis allows of no attempt to treat the hernia radically. 5. Taxis may bring about reduction *en masse*. Against operation, on the other hand, he cited:—1. Operation involves loss of time in preparing for it. 2. Operation usually requires a general anæsthetic. 3. Operation may cause a risk of septic peritonitis. 4. Operation necessitates confinement to bed. 5. Operation may cause the aperture to be enlarged. 6. Operation may be greatly objected to by the patient. Mr. Eccles gave it as his opinion that children with strangulated hernia should be but rarely subjected to operation, for the gut can nearly always be returned by gentle taxis and is seldom very acutely strangled. Again, old persons the subjects of chronic lung trouble should be treated, if feasible, by taxis alone. Almost all other cases of strangulated herniæ he averred might be safely dealt with by operation and he considered that the old adage, "When in doubt operate," might be more widely extended.—Dr. F. H. ALDERSON entirely agreed with Mr. Eccles as to the rarity with which operation was required in the strangulated herniæ of infants.—Mr. KEETLEY alluded to the difference of taxis under various conditions, but gave it as his opinion that operation was indicated in nearly every case of strangulation.—Mr. G. E. TWYNAM thought it very doubtful that operation could be carried out with success in many cases where assistance was difficult to obtain. He thought that circumcision should always be performed in male infants who had strangulated hernia with a view to the cure of the protrusion.—Mr. MALLAM inquired whether it was common to find that the fluid reduced by taxis gave rise to peritonitis.—Dr. R. D. BATTEN and the PRESIDENT having joined in the discussion, Mr. ECCLES replied.

Mr. A. H. TUBBY read a paper on the Surgical Treatment of Spastic and Infantile Paralysis. He said that the object of the paper was to show that certain cases of infantile spastic paralysis might be much benefited by the division of contracted structures and he further wished to bring forward some comparatively new features in the treatment of extreme cases of infantile paralysis. After describing types of cases of infantile paralysis he thought that the results of operation justified the surgical interference in these children. The method of treatment was to divide the tensor vaginæ femoris, the sartorius, and adductor tendons at their pelvic attachments, as well as the hamstrings and the iliotibial band at the knee, and to apply weight extension for a month, and then to sever the tendo Achillis and finally to maintain the rectification by means of a light apparatus. In the treatment of severe cases of infantile paralysis Mr. Tubby advocated tendon-grafting and arthrodesis. He pointed out the indications for, and limitation of, tendon-grafting. Arthrodesis on the ankle was in his opinion a successful method of dealing with the flail-like joints resulting from infantile paralysis and he described the mode in which the operation was performed.—Mr. MCADAM ECCLES congratulated Mr. Tubby on his paper. He asked him whether the length of the sartorius muscle in cases where it was implanted into the tendon of the quadriceps extensor was of much importance.—Mr. KEETLEY thought that much benefit arose in cases of spastic paraplegia by the division of contracted tendons. He was doubtful of the utility of arthrodesis of the hip-joint and he further questioned whether stiff knee- and ankle-joints were to be regarded as beneficial in many instances.—Mr. TUBBY replied.

BIRKENHEAD MEDICAL SOCIETY.

Rectal Disease.

A MEETING of this society was held on April 15th, the President, Dr. R. SYDNEY MARSDEN, being in the chair.

Dr. W. H. ANDERSON read clinical notes and showed a specimen of Perforating Gastric Ulcer.

Mr. MITCHELL BANKS read a paper on Practical Experiences in Rectal Disease. With regard to the operation to be employed for the destruction or removal of hæmorrhoids he thought there were three or four means which might each be employed with advantage by a surgeon who had familiarised himself with one particular method and had acquired dexterity in its use. For himself he had been a consistent advocate of the clamp and cautery operation introduced by Mr. Henry Smith and had certainly done it some two or three hundred times at the lowest estimate. What greatly induced him to adhere to it was the remarkably satisfactory results which followed, for never once had a patient come back with a return of his hæmorrhoids. Whatever drawbacks might be urged against the operation he was absolutely certain of its permanently curative effect if properly done. After the operation he was in the habit of tying into the bowel a short flanged glass tube. This allowed the passage of flatus, which was one of the things which often greatly worried patients for the first twenty-four hours. It, moreover, enabled the blood to escape if any secondary hæmorrhages occurred and so warning was given. He had heard surgeons state that they never had such a thing as secondary bleeding. He could only say that if they went on operating long enough their unfortunate case would at last turn up. To minimise the danger of this after clamping the hæmorrhoid he rarely cut it off, but slowly frizzled it up into a leathery state by repeated applications of the cautery at not too great a heat. Coming to the subject of the removal of

[1] Brit. Med. Jour.

the rectum for cancer by Kraske's method his experience of it made him think that it was one of the most valuable operations for cancerous disease of recent origin because the sacral glands did not seem to be so early affected as in many other parts of the body and so a chance was given for immunity to follow free local extirpation. Operations for cancer of the tongue and mouth generally were most disheartening from the early involvement of the cervical glands, and he thought a great deal of ingenuity and labour were being thrown away over attempts to remove cancer of the stomach and pylorus where recovery—followed by subsequent immunity—was such a rare startling occurrence that it only showed how few were the really successful results. What was so remarkable in the modern rectal operations was that one might pull down even the sigmoid flexure into the wound, while the opening of the peritoneum seemed to be productive of very little danger. His own view was against a preliminary colotomy. As a rule a patient required every particle of strength to stand up against an extensive removal of the rectum, for the bleeding alone at the time of operation was often most alarming. Of course some time would yet have to elapse before the full value of the operation was known, but he could mention the case of a woman who was well and managing the affairs of a considerable household eight years after the operation and of a man who was actively doing the work of surveyor to a marine insurance company after three years. Both were quite free from return. Mr. Banks next drew attention to certain very severe cases of pruritus, which defied all ordinary remedies and which reduced the patients to the most miserable condition. He instanced three patients, of whom one was a merchant in a large way of business who at length was quite unable to attend to it and another a man who came all the way to England from South Africa in search of relief from his complaint. They were all permanently cured by a smart application of the actual cautery around the anus and for a short distance within it.

A hearty vote of thanks was accorded to Mr. Banks for this interesting paper.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Surgical Instruments and Apparatus.—Presidential Address.

THE seventh and last meeting of the session of this society was held on May 6th at the Royal Kent Infirmary, the President, Mr. W. ARBUTHNOT LANE, being in the chair.

Before the meeting Messrs. Maw, Son, and Thompson gave an exhibition of Surgical Instruments and Apparatus.—Dr. Prior Purvis was unanimously elected as an honorary member.

Mr. ARBUTHNOT LANE delivered an address on the Principles that should Guide us in Operations for Malignant Diseases. He pointed out that the two chief indications were the complete removal of the growth at all costs, modified, of course, by the wishes of the patient, who must be made fully aware of the risks and advantages associated with any particular procedure, and the ensuring to the patient of a minimum of discomfort and pain in consequence of the operation. Mr. Lane illustrated his meaning by descriptions of operative measures for the removal of the larynx, tongue, breast and rectum, which were based on the application of these two principles.—Mr. LANE then read a paper on the Treatment of Ununited Fractures by Steel Screws, illustrating the cases by radiographs.

Mr. BIDWELL, Dr. DOCKRELL, and Dr. TOOGOOD discussed the papers and Mr. LANE replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—The Acute Pneumonia of Childhood.—Paroxysmus Podagræ.

THE seventh ordinary meeting of this society was held on May 4th, Dr. JAMES CARMICHAEL being in the chair.

Dr. SCOTT SKIRVING exhibited a boy, aged five and a half years, after operation for Ectopic Perineal Testicle. The history was that a month previously he had received a kick from another boy on the perineum. Three weeks later pain on micturition was complained of in the mornings. A swelling was then noticed on the right side of the perineum extending from the margin of the scrotum nearly to the anus. The testicle on the left side was wanting. The swelling was cut down upon and a condition resembling ordinary congenital hernia was met with, without the presence of gut, however. There was a free communication with the abdominal cavity. The sac in its descent had entirely missed the scrotum and had wandered into the perineum. It was found impossible to place the testicle in the scrotum. It was therefore removed and a radical cure effected. The tunica vaginalis was considerably thickened.

Dr. WILLIAM TAYLOR exhibited an Electro-thermogen devised by himself and used in the case of neuralgia. Dr. Taylor had suffered himself from neuralgia and found that superficial remedies had only a transient effect. Dry heat alone allayed the pain for a time. He argued that if a damp, cold air current caused the affection then a hot, dry air current might cure it, so he set himself to devise an instrument to generate a hot stream of dry air. A long coil of brass tube was first tried. This was heated by a gas jet and air was pumped through it by a bellows. Such an arrangement is expensive and soon becomes too hot to be handled. Dr. Taylor then devised his electro-thermogen. There is a metallic base which contains clock-work, which causes an air-fan to rotate in order to produce the current. Above this is a chamber into which a glass tube, suitably bent to direct the current, is inserted. Inside this tube is another smaller glass tube around which a platinum wire is coiled in a wide spiral. An electric current is made to traverse this coil and so the air as it passes through the tube is suitably heated. A suitable current is got from the ordinary electric mains. This machine has been found very useful in the treatment of neuralgia. It sometimes produces a blister, however, and Dr. Taylor was surprised at the amount of thermal anæsthesia which it produced. Several cases of neuralgia were related where cures were effected after a single or at most only a few applications. In toothache and twitching of the face it had also shown good results. As a vapouriser it was also useful and in a case of gouty asthma and clergyman's sore throat it had proved of service. A large form of the apparatus was also shown for the treatment of lumbago, torticollis, &c.

Dr. JAMES CARMICHAEL contributed a paper on Acute Pneumonia of Childhood. He noted that the etiology of the disease in children was the same as in the adult and yet the clinical symptoms were widely different. The terms "lobar" and "lobular" were serviceable but gave no information as to the real pathological conditions which were present. Bacteriology had thrown much light on this disease and on its infective nature. Bacteria or the toxins produced by them give rise to the chief symptoms and to the endangering of life. This was shown by the frequency of cerebral symptoms together with the slightness of the pathological conditions present in many cases. In pneumonia the disease is short and the crisis is well marked. Is this due to the short life-history of the organism or to anti-toxins which are readily formed? Dr. Carmichael then proceeded to give a detailed classification of the acute forms of pneumonia founded on their pathology and bacteriology. The bacteriology of the disease was next discussed, and Netter was quoted as having found in 42 cases (of which 25 were primary) 10 cases in which Friedländer's pneumococcus was present; streptococci in 8 cases alone; staphylococci in 5; and Fränckel's capsuled coccus in 2. In 17 there was a mixed infection. In secondary cases of pneumonia the micro-organisms are still more numerous—streptococci and staphylococci pneumoniæ—showing a mixed infection. In the pneumonia of influenza Pfeiffer's bacillus and others have been observed as well as the bacterium coli commune. In pneumonia as a result of diphtheria Löffler's bacillus alone or along with other organisms has been found. Dr. Carmichael then described fully the pathological anatomy of the disease as regards the distribution of 142 hospital cases which he had himself observed and all of which had recovered; 107 showed features of a catarrhal nature and all occurred among children under five years of age; 35 cases were of the fibrinous variety. In 83 of the catarrhal cases the termination was by lysis, while in 24 there was more or less decided crisis. In 53 cases both lungs were affected. As regards the clinical aspect primary acute pneumonia is usually epidemic and this is well seen in hospital work. It is highly probable that

it is infectious, but he had found no proof of this from his own observations. There had been a very large number of cases admitted to his wards during the last six months. Catarrhal pneumonia is a disease essentially of infant life. In duration it varies from ten days to many weeks, chronicity being frequent and tuberculosis not uncommon as a result. Pleurisy is usually present to a greater or less extent and is usually localised. The physical signs are well defined and regular. The temperature rises and remains so until the fifth or seventh day, when the crisis occurs. If it does not then fall the opposite lung has become involved or there has been an increase of the pleural exudate. Pneumonic fever is a good name for catarrhal pneumonia. All forms of pneumonia are due to a common cause. Why should the catarrhal form be found in children under five years and the fibrinous variety in older children or adults? In infants the minute bronchi and alveoli are the most delicate parts of the lung. The alveoli are not developed at the fifth month of fœtal life, and it is not until the fourth or fifth year that they are fully developed. Prior to this period they are much smaller and the walls are relatively thicker; the vessels are very abundant and the epithelial cells are very numerous and readily proliferating. Here is a ready explanation of the pathological condition produced by the disease. The greater vascularity of the walls, the immature nature of the epithelial cells, and the presence of interstitial cells all present less immunity to the infective process. The anatomical conditions thus differ from those of the adult. There are three types of catarrhal pneumonia: (1) those without signs; (2) small areas of consolidation—lobular distribution; and (3) large areas of distribution—lobar. The symptoms are much more constant than the physical signs. They form a marked similarity in different varieties enabling the physician to diagnose the case without physical examination. The mere inspection and history allow of a probable diagnosis. Of the means of physical examination auscultation is by far the most reliable. Percussion is unreliable unless large areas are involved. One ought to examine carefully with the stethoscope every part of the chest, as the area involved may be very small and just under the end of the instrument. Auscultation must be relied on for diagnosis. The breathing is broncho-vesicular with sometimes few or no râles over the centre of the area. The adventitious signs are most distinct over the periphery of the areas. 95 per cent. of the fibrinous cases recover, while there is a mortality of 60 per cent. in the catarrhal. As there has not yet been discovered an antitoxin no special treatment exists for acute pneumonia. Hygiene and diet are all important. The use of a tent bed with towels moistened in an antiseptic solution as creasote are the means used by Dr. Carmichael. In severe cases with cyanosis he has found benefit from inhalations of oxygen. Poulticing is now discarded, but stimulating applications rubbed over the chest for half an hour or a pneumonia jacket of Gamgee he has found beneficial. Local and general diaphoresis relieve the lungs. As regards drugs none is of any special value. Liquor ammoniæ acetatis and spiritus ætheris nitrosi together with alcoholic stimulation are of great value, specially in broncho-pneumonia; strychnine given with alcohol has been of great use and seems to act better with infants than with adults. Belladonna also greatly benefits infants when employed during the early stages of the disease. It is, however, of no use during the later stages. Digitalis should not be used as a routine drug but only in special circumstances. Large doses of antipyretics are contra-indicated and are often harmful. In small doses they are useful in allaying restlessness. Hyperpyrexia is best treated by the cold pack or bath. As regards expectorants, vinum ipecacuanhæ, squills, tartar emetic, &c., are still largely used, but in Dr. Carmichael's opinion harmfully. Children require stimulation and not depressants.

Dr. GEORGE W. BALFOUR next read a paper entitled "A Fit of Gout (Paroxysmus Podagræ): a Pathological Study." He noted the pathological points observable during an attack, drawing attention to the facts that it differed from ordinary inflammation in never ending in suppuration. The veins of the joint become turgid at an early period and cause attention to be first drawn to the part. The turgescence of these veins lasts until the seizure is over. Instead of there being heat in the joint so affected its temperature is subnormal. The urate of sodium which infiltrates the tissues shows that it is a specific form of inflammation. Dr. Balfour went on to show that a thrombosis of the small vessels of the joint would explain all the symptoms and thought that the lowering of temperature of the part was due to the stasis of the circulation. As regards the prophylaxis the attack may frequently be warded off by exercise. Walking may help to break up the thrombi already beginning to form and so lessen the risk of an attack. In cases where the attack has already begun friction and compression are of great value.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Serum Diagnosis of Typhoid Fever.—Mortality of Children.

A MEETING of this society was held on April 29th, Dr. H. C. TWEEDY, the President, being in the chair.

Dr. MCWEENEY demonstrated a Modification of the Serum Reaction in Typhoid Fever which he had introduced with a view to clear up the diagnosis in cases which did not give the agglutination phenomenon with sufficient distinctness. He causes the typhoid bacillus to grow in a hanging drop of broth containing a small percentage (generally 1 per cent.) of the suspected serum. After four hours at 37° C. the preparation is examined, when, should the serum be from a typhoid case, the bacilli will be found to have grown out into beautiful chains which at the end of twenty-four hours are exquisitely twisted and convoluted; motility is quite absent. If, on the other hand, the serum is non-typhoid the bacilli are separate and freely motile. They are usually short, but occasionally grow out into filaments especially if the temperature is low; but these filaments must be carefully distinguished from the chaining which takes place with the homologous serum.

Dr. LANGFORD SYMES contributed a paper on the Mortality of Children in Ireland. From his estimate of ten years ending Dec. 31st, 1896, it appears that in Dublin city out of every 1000 children born there die in the first year 171·2; and in every 1000 total deaths, 306·2 are children under five years of age. In Belfast the death-rate of children is enormous. In every 1000 total deaths in that city, no less than 519·8 are those of children under five years of age. Of the actual registered causes of death for all children in the whole of Ireland the following were the eleven chief diseases found to produce this infantile mortality in their order of importance. They are identically the same diseases for both ages, but in varying proportions:—

UNDER ONE YEAR.		UNDER FIVE YEARS.	
Cause of death.	Deaths under 1 year.	Cause of death.	Deaths under 5 years.
1. Debility, atrophy, inanition	29,136	1. Debility, atrophy, inanition	32,062
2. Convulsions	20,764	2. Convulsions	25,261
3. Bronchitis	14,017	3. Bronchitis	24,775
4. Diarrhœa & dysentery	5,762	4. Whooping-cough ...	11,456
5. Whooping-cough... ...	4,893	5. Diarrhœa & dysentery	8,383
6. Premature birth	3,827	6. Tabes mesenterica ...	7,564
7. Tabes mesenterica ...	3,542	7. Measles	7,557
8. Pneumonia	2,619	8. Pneumonia	6,868
9. Tuberculous meningitis	1,755	9. Croup	5,509
10. Measles	1,691	10. Tuberculous meningitis	5,089
11. Croup	1,589	11. Premature birth	3,827

Dr. Symes pointed out that the terms "debility, atrophy, inanition" were too indefinite for a medical certificate and that the word "convulsions" denotes a symptom rather than a disease.—Dr. GRIMSHAW (Registrar-General), Dr. DOYLE, Dr. FALKINER, Mr TURNER, and the PRESIDENT took part in the subsequent discussion.

ERRATA.—In Mr. W. G. Spencer's case of Gangrenous Appendicitis described in THE LANCET of May 7th, p. 1258, it should have been stated that the patient had "no previous attacks" of pain. The case of Empyema said on p. 1259 to have been shown by Mr. Spencer was shown by Dr. de Havilland Hall.

ABERDEEN UNIVERSITY CLUB, LONDON.—The annual meeting and May dinner of this club will be held in the Holborn Restaurant, on May 18th, at 7 P.M. The chair will be taken by Colonel Sir William S. Bissett, R.E., K.C.I.E. Members desiring to be present are requested to communicate with the hon. secretaries, Mr. J. Gerard Laing, 2, Brick-court, Temple, E.C., and Dr. James Galloway, 54, Harley-street, W.

Reviews and Notices of Books.

Abdominal Surgery. By J. GREIG SMITH, M.A., M.B., C.M. Aberd., F.R.S. Edin., Surgeon to the Bristol Royal Infirmary, Professor of Surgery, University College, Bristol. Sixth Edition. Edited by JAMES SWAIN, M.S., M.D Lond., F.R.C.S. Eng., Professor of Surgery, University College, Bristol, Assistant Surgeon to the Bristol Royal Infirmary. Bristol: J. W. Arrowsmith. London: J. & A. Churchill. 1897.

THE editor tells us in the preface that in less than a year from the publication of the fifth edition of this work it became necessary to issue a sixth, so that little change in the text has been necessary, though he has endeavoured to keep the book abreast of any advance in the subject. The present edition has been prepared almost entirely by Mr. Swain, as he tells us that scarcely a hundred pages of it had been set up before the lamented death of Mr. Greig Smith took place. Mr. Swain had, however, evidently done much of the work required for the preparation of the fifth edition, and besides has this additional qualification for editing the present edition—that he constantly assisted Mr. Greig Smith both in private practice and at the Bristol Royal Infirmary. When a book has reached a sixth edition its position is generally assured, and little notice of it is needed at the hands of the reviewer, but we may say that we think the book deserves its success and that it has rightly come to be regarded as a standard work on the subject of which it treats. Surely, however, in the preliminary chapter on the Diagnosis of Abdominal Tumours more space should have been given to the consideration of the commonest of all abdominal "tumours"—namely, the pregnant uterus at its various stages of development. All those who have had a large experience in abdominal cases know how frequently mistakes are made in regard to pregnancy. Such mistakes may almost always be avoided by keeping the possibility of pregnancy in mind and carefully looking for the various signs of that condition. But here the matter is dismissed in a few lines. We may add that in the description of total hysterectomy for fibroids the writer does not appear to be familiar with Mr. Christopher Martin's paper on the subject. According to the method there described there is no need for suturing the vaginal vault; a gauze drain is merely pulled through from above and about an inch of the gauze is left projecting into the peritoneal cavity.

A Manual of Dental Anatomy, Human and Comparative. By CHARLES S. TOMES M.A., F.R.S. With 263 Illustrations. Fifth edition. London: J. & A. Churchill. 1898. Pp. 586, with Index. Price 14*s*.

THE fifth edition of this standard work on Dental Anatomy has been brought thoroughly up to date and is a distinct advance on any of the previous editions. At first written with a view of providing the dental student with the requisite knowledge for his qualifying examination it has since become a text-book for the student of biology in general. This fact, combined with the rapidly increasing literature on the subject, has, as the author points out, "greatly enhanced the difficulty of bringing the book up to date." It is, however, needless to say that the work of editing has been carried out in an admirable way. In the chapters on Enamel and Dentine, more especially the former, there is much that is new, and in both these chapters a number of new illustrations have been introduced. The chemistry of the tooth tissues has been more fully dealt with than in former editions, and it is interesting to note that the author's investigations go to show that enamel is practically devoid of organic matter, the portion previously considered to be organic being in reality water; while in the dentine a large portion of the previously supposed organic matter is really water held in chemical combination with the lime salt. The chapter on Calcification also contains a large amount of fresh matter in addition to new illustrations. The portion of the book which includes Comparative Odontology includes an account of all fresh knowledge that has accumulated since the fourth edition. If we might make a suggestion it would be that in future editions the chapters on the Pulp and Alveolo-dental Membrane should be more fully illustrated.

Twentieth Century Practice of Medicine. Edited by THOMAS STEDMAN, M.D. Vol. XI., Diseases of the Nervous System. London: Sampson Low, Marston and Co. 1897.

THE list of writers in this most comprehensive work is one which ensures interesting and valuable contributions. It includes Dr. Lloyd, who occupies almost half the volume with an account of the Diseases of the Nerves—Cerebral, Spinal, and Sympathetic; Dr. Bruns of Hanover and Dr. Windscheid of Leipsic, who write on Diseases of the Spinal Cord; Professor Möbius whose article on Tabes Dorsalis is a valuable feature of the volume; Dr. Dercum and Dr. Mills, who between them are responsible for the account of the Trophoneuroses; Professor Strümpell, who contributes a short article on the Combined System Diseases of the Cord; and Dr. Witmer, who is charged with the psychological work.

Dr. Lloyd's article on Diseases of the Nerves is, as we have said, of considerable length, but it is admirable in every respect, dealing fairly with the physiology so far as it is necessary and with the various general pathological conditions affecting nerve trunks, and considering also almost every nerve which is liable to isolated disease. The section dealing with the optic nerve is a particularly good one; in those dealing with the third, fourth, and sixth we miss the usual elaborate descriptions and puzzling diagrams of the different varieties of diplopia, and in that dealing with the olfactory nerve the author has omitted to mention the not infrequent anosmia which arises, presumably as a result of pressure in certain cases of intracranial tumour. It would be an invidious task to pick out small blemishes in such an article as Dr. Lloyd's, however, and we venture to think that it will remain for some time the most authoritative pronouncement on its own subject.

It seems hardly necessary for the Trophoneuroses to have been divided up as they have been. Dr. Mills takes all the trophoneuroses except scleroderma, acromegaly, and adiposis dolorosa which are allotted to Dr. Dercum. Among Dr. Mills's subjects is facial hemiatrophy and, considering the close connexion of this condition with morphœa and scleroderma, it seems a pity that these conditions should not have been dealt with by the same writer. The articles, however, in both sections are very complete.

Dr. Bruns' and Dr. Windscheid's section on Spinal Cord Diseases is one of the most important in the volume. The section dealing with injuries is particularly good, but one statement, which requires explanation, arrested our attention, viz.—"It (a lesion) is sure to be fatal when with lesions in the dorsal and cervical cord the tendon reflexes remain absent beyond the time of a possible effect of shock and the paralysis of the leg continues flaccid." It is now well established that the reflexes may be absent for months and yet return and it can scarcely be claimed that the effects of shock persist during that time. Amongst the other articles in this section which strike the reader as particularly good are those on tumours of the cord and meninges, and on myelitis.

Professor Möbius's article on Tabes Dorsalis is a valuable

contribution to the volume. It is characterised by profound and accurate knowledge and by philosophical breadth of view and it is particularly sound in reference to treatment.

Professor Strümpell's article on the Combined System Diseases is distinctly disappointing. Dr. Witmer's treatment of the psycho-physiological problem resolves itself into an interesting dissertation on the nature of pain and other abnormal sensations. The volume is illustrated, but not profusely, and the pictures are not all worthy of the text.

A Manual on Dental Metallurgy. By ERNEST A. SMITH. Illustrated. London: J. & A. Churchill. 1898. Pp. 272 Price 6*s.* 6*d.*

THIS excellent little book will fill a want long felt and is designed primarily for students preparing for the dental examination, the subject matter being largely based on the new syllabus of dental metallurgy issued by the Royal College of Surgeons of England. The opening chapter contains a concise account of the physical properties of the metals; then follows an account of the action of certain agents on metals, and in Chapter III. an account of "alloys" including their properties and preparation is given. The metals in common use in dental practice are each described and a special chapter is devoted to the question of Dental Amalgams. With a view of rendering the book as practical as possible the author has enumerated a list of 100 experiments which may readily be carried out in a well-equipped dental laboratory, and anyone faithfully carrying out this list cannot fail to obtain a good and clear insight into the working of the various metals treated. There is a useful appendix containing information as to atomic weight, metrical measures of weight, capacity, &c.

LIBRARY TABLE.

Llangammarch Wells as a Health Resort. By W. BLACK JONES, M.D., B.S. Lond., D.P.H.—Dr. Black Jones is the resident physician to the Llangammarch Wells and so has exceptional opportunities of observing the action of the waters on patients who undergo the treatment. The most interesting constituent of these waters is a salt of barium and a full analysis was published in THE LANCET of Nov. 24th, 1894. Numerous patients suffering from dilated heart have received benefit from the use of these waters, which have also been found useful in other pathological conditions, such as gout, rheumatism, and lithæmia. From Dr. Black Jones's account of the place it would appear to be equal in attractiveness to many more distant and expensive foreign health resorts.

Allgemeine Physiologie: Ein Grundriss der Lehre von Leben. Von MAX VERWORN. Zweite Auflage. Jena: G. Fischer. (*General Physiology: An Outline of the Science of Life.* By MAX VERWORN. Second edition. Jena: G. Fischer. 1897. Price 15*s.*)—We need do little more than direct attention to the publication of a second edition of this thoughtful and remarkable work which was fully noticed in these columns on its first appearance. Its general purport is to solve the riddle of existence by reference to known facts of the nature of living matter, speculations as to its origin, and the teachings of physiological science as to its properties and phenomena. The merit of the work is that it does not deal with the subject in the abstruse manner which is deemed by some necessary to the exposition of themes of this order, but that it brings the latest teachings of science clearly and succinctly before the reader. So that in a sense it may be said to be of the class of "popular scientific" writings, which after all is no disparagement, since if science is incapable of being made plain to the multitude it is of small practical value. We learn from the preface that an English translation is in preparation and we have no doubt that the book is one which will then become more widely known in this country than it is at present.

JOURNALS.

The Practitioner for May has a delightful quotation from a French medical journal which the editor brings forward as an example of style. We have seen nothing like it since the gems which used to appear in the now, we believe, defunct *United Ireland* in the early "eighties." Dr. R. Farquharson contributes a very readable paper on the Treatment of Acute Disease from the Patient's Point of View which throws some light upon the practice of bygone practitioners, and Dr. D. J. Leech considers the Treatment of Bronchitis by Drugs. A very general mistake is, he thinks, to give diaphoretics and stimulants such as carbonate of ammonia in too small doses. He points out that in the new Pharmacopœia the dose of the liquor ammonii acetatis is given as up to six drachms. That admirable physician, the late James Andrew, used always to say that for a cold or to get relief in bronchitis there was nothing like "a good drink of H.A.A.," the "haustus ammonii acetatis" of the St. Bartholomew's Hospital Pharmacopœia.

The Journal of Physiology. Edited by MICHAEL FOSTER, M.D. Lond., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XXII., No. 6. London: C. J. Clay and Sons. April, 1898. Price 5*s.*—This number completes the twenty-second volume of the Journal and contains, in addition to the Proceedings of the Physiological Society, the following articles: 1. O. F. F. Grünbaum on Intermittent Stimulation of the Retina (part ii., with 5 figures in the text). The author shows *inter alia* that on increasing the intensity of an intermittent stimulus beyond a certain point a further increase in intensity allows a decrease in frequency without destroying the sensation of fusion. 2. On Urobilin (part ii.)—The Percentage Composition of Urobilin, by F. Gowland Hopkins, M.B., B.Sc. Lond., F.I.C., and Archibald E. Garrod, M.A., M.D. Oxon., F.R.C.P. Lond. They find the percentage composition of urobilin to be C 63·58 H 7·84, N 4·11. 3. Some Improved Methods of Gas Analysis, by John Haldane, M.D. Edin., F.R.S. (with 6 figures in the text). 4. Contributions to the Physiology of Unstriated Muscular Tissue (part iv.)—The Action of Electrical Stimuli upon the Œsophagus of Aplysia depilans and Aplysia limacina, by Dr. Philip Botazzi, Docent of Physiology in Florence. The movements referred to seem to be purely myogenic and resemble those of the heart, but there is no refractory period. No nerve cells can be demonstrated histologically in the œsophagus of these animals.

In the *Phonographic Record* for May Sir William Gowers condemns the treatment of syphilis by remedies given continuously over a long period. He says that mercury should be given for from four to six weeks after the gums are affected by it, when iodide may be given systematically for four months during the first year and then every six months for three weeks for three or four years after the first symptoms. Mr. Peyton Beale puts forward a plea for the use of the horseshoe pad in hernial trusses; there is a well-reported clinical lecture on a Case of Pseudo-hypertrophic Muscular Paralysis, as well as short notes on the Duration of the Lead Line on the Gums and a Case of Spontaneous Cure of a Ranula.

ROYAL INSTITUTION.—On Friday evening, May 6th, Mr. E. A. Minchin delivered a discourse on Living Crystals, meaning thereby the spicules of calcium carbonate embedded in various species of sponge. The optical phenomena produced when those spicules are examined by polarised light are similar to those obtained with the mineral calcite.

THE LANCET.

LONDON: SATURDAY, MAY 14, 1898.

WE need not apologise for reverting to the highly important announcement made by the Secretary of State for War at the banquet given by the Lord Mayor to the medical profession at the Mansion House last week. The nation—as well as the officers of the Army Medical Staff and the profession generally—has, in our opinion, to be congratulated on the generous and statesmanlike policy so unequivocally enunciated by Lord LANSDOWNE on that occasion, for we are living at a time when "wars and rumours of wars" abound, and this country has always to be on the alert to maintain her position in the international struggle for existence. There are, moreover, few households or families which have not some member connected either with the army or the navy and it is consequently a matter of national concern that both of them should possess thoroughly efficient medical services not merely in times of war, when everyone recognises the necessity of sound surgical skill promptly applied, but in times of peace, particularly at remote and outlying stations where no other medical help is available. The functions of army medical officers do not merely embrace the treatment of disease and its prevention, but upon them is laid the entire charge of the sick and wounded, their succour and surgical aid in the field, their transport and the organisation of hospitals for their reception, in addition to the discharge of administrative and disciplinary duties of an extensive and complicated character. It cannot be denied that these are weighty and responsible duties, calling for high qualifications on the part of those undertaking them. For many years past it has been notorious that, although no complaint has been made about the pecuniary inducements offered by the army medical service, it has, nevertheless, failed to attract either a sufficient number of medical candidates or those of the right stamp. We earnestly hope and believe that that time is past. There is no need to go into the causes or the conditions which rendered the army medical service distasteful, seeing that Lord LANSDOWNE has now happily promised to alter all this and has determined, as he said, that there shall be no failure either in theory or in practice to treat medical officers with all the respect to which they are entitled.

Lord LANSDOWNE has proposed to make a fresh start and to form a consolidated army medical corps by welding together the Army Medical Staff and the Medical Staff Corps under the title, by HER MAJESTY'S command, of the "Royal Army Medical Corps." The officers of the newly-formed corps are to have actual army rank and are to bear exactly the same military titles as other officers of the army up to the rank of colonel, with the reservation—a perfectly reasonable one under the circumstances—that above that rank the compound and distinctive title of "Surgeon-General" shall be adopted, but carrying with it the rank and precedence of a general officer in the army. Sir SAMUEL WILKS and Sir WILLIAM MACCORMAC, the respective Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England, both spoke in highly appreciative terms of Lord LANSDOWNE'S announced intentions regarding the Army Medical Service. Sir WILLIAM MACCORMAC in particular expressed himself very clearly and emphatically on this point and he is in an excellent position to form an accurate and just judgment in regard to it, for he has had exceptional opportunities of knowing the requirements of the army medical officers. On a memorable occasion long ago he most successfully vindicated their labours and placed on record the admirable results which followed them in the Egyptian campaign of 1882. We have no doubt also that should Sir WILLIAM THOMSON, the President of the Royal College of Surgeons in Ireland, express his opinion upon the nature and extent of the Secretary of State's concessions he will entirely endorse the views which have been expressed on this side of St. George's Channel. Nothing could have been better than the frank and generous tone in which Lord LANSDOWNE recognised the great value of the services performed by medical officers, and the share which they took in all the risks and hardships of war. He has, in our opinion, dealt with their grievances in a wise and statesmanlike spirit and has yielded all that can be reasonably demanded to make their position secure and satisfactory. It should not be forgotten, too, that in a number of other respects several important and much needed changes have also been introduced of late in the interest of the Army Medical Staff. Assuming, then, that the declared intentions of the War Minister are to be embodied and promulgated in authoritative official form, as they undoubtedly will be, we need scarcely ask ourselves what should be the position of the profession in regard to the new order of things.

We can have no hesitation in declaring that the members of the Army Medical Staff should accept these concessions in a sincere and honest spirit and that our medical schools and the universities and the profession generally should do all in their power to make the new Royal Army Medical Corps a success. To become an officer of such a corps is a worthy object of ambition. The prospect of seeing the world, of taking part in the dramatic and chequered scenes of military life and adventure, and the probable opportunity of attaining rank and titular distinction, will always have attractions for the young, the healthy, and the enterprising. The military position of medical officers will henceforth be as good and secure as it can be made officially, and as regards social status it must always be borne in mind that every officer's position, to whatever branch of the service he may belong, must depend upon himself. It is beyond the power of any Government to confer personal qualities by any mere titular rank or distinction. All that a Government can do is to insure that a young medical officer shall occupy as good a position as any other officer of corresponding rank; for the rest he must depend upon himself. The

medical service is now an integral part of the army and the medical officer's position is henceforth to become a thoroughly recognised and established part of the military machine. This being so it is for the members of that service to show that they are proud of their medical calling and ambitious of success in the exercise of it for the benefit of all committed to their care and thereby to prove how groundless and calumnious have been the fears of those who have asserted that should the desired concessions be granted their professional duties would not be, as they assuredly should be, the first and dominating consideration. It stands to reason that commanding officers and others are only too glad to have the services of really capable medical officers for the care of themselves and the men serving under them; and as regards the latter—the rank and file of the British army—TOMMY ATKINS is never backward in recognising and in gratefully appreciating the services of those on whom he can confidently rely when he is sick or wounded. Very many years have elapsed since THE LANCET first advocated the formation of a Royal Medical Corps for the army on the lines of the Royal Engineers. This has now been accomplished and we feel assured that medical officers and the profession in general will do all in their power to aid Lord LANSDOWNE in carrying out his policy to a successful issue.

THE Lunacy Bill was read a second time in the House of Lords on Thursday, May 5th. The remarks of the Lord Chancellor in moving the second reading were conciliatory in character and indicated an evident desire on the part of the Government that the Bill should pass into law during the present session. The Bill is substantially the same as that of last year, and with few exceptions no material alteration is to be detected in its main features. Some improvements are, however, noticeable. Clause 29 of last year's Bill, with its ridiculous enactments of fine and imprisonment, has been swept away. Asylum officials are therefore no longer confronted with the remote contingency of penal custody *plus* hard labour on account of the occurrence of a clerical error in a certificate. The clause in question was so loosely drafted that no clear distinction was made between wilful mis-statement and negligence. There still appears to exist a lurking belief that the safeguards for preventing the disappearance of presumably sane persons within the walls of a lunatic asylum are not quite efficacious. This applies more particularly to the employment of urgency orders. The alleged abuse of these orders in certain cases was alluded to in condemnatory terms during the second reading debate in the Upper House. No laxity in respect to these urgency orders is likely to occur in future, for the Bill enacts that the certifying person shall be held responsible for any mis-statement and shall be compelled to state his reasons for the necessity of the order on the face of the certificate. It is well known that many medical men are averse to signing lunacy certificates of any description, and it is very questionable whether this stringent provision will conduce to the speedy removal and safe custody of dangerous homicidal and suicidal patients. The duration of an urgency order will in future be four days, instead of seven days as hitherto.

Not unnaturally the interest and attention of asylum officials will centre round the superannuation clauses. In the Bill of 1897 it was proposed to make the pension scale similar to that of the Poor-law Officers Superannuation Act, 1896. This caused great dissatisfaction, and the opposition aroused was so strong that it may be said to have led to the withdrawal of the Bill last session. The step undoubtedly was a retrograde one, and the result of its adoption could only have been to lower the general efficiency of the service. The tenour of the clauses of the present Bill is distinctly more satisfactory. The main point is that pensions are made obligatory. (The same held good in last year's Bill.) The scale of the Poor-law Officers Superannuation Act, 1896, is adhered to, but only as a minimum. In the second reading debate the Lord Chancellor was careful to point out that this minimum was only offered as a suggestion, and, by inference, that it was capable of adjustment. Good grounds therefore exist for hoping that it will be raised. By the provisions of the Bill a discretionary power seems to be vested in the visiting committees of asylums to increase the amount of pension over and above the minimum stated. It would be well if they were authorised to grant retiring allowances to their officers after fifteen years' service. On account of the peculiar nature of their duties, and the painful consequences which sometimes ensue from prolonged and close association with the insane, the medical officers of asylums have strong grounds for claiming this privilege—indeed, the Select Committee of the House of Commons, in 1860, upheld this contention. Twenty-five, or at the most thirty years' continuous service, not necessarily in the same asylum, should entitle them to a maximum superannuation allowance not exceeding two-thirds of their total pay and emoluments. A fixed scale of pension has been advocated in certain quarters—viz., one-fortieth of the total pay and allowances for each year of service to those whose duties bring them into constant and direct contact with the insane, and one-fiftieth to other officers and servants—the recipients, except in the case of incapacity from confirmed illness or infirmity, to be not less than fifty years of age, and to have at least fifteen years' service; no pension to exceed two-thirds of the total pay, &c. In the event of any fixed scale being formulated, this scheme is deserving of serious consideration. Failing the adoption of a fixed and uniform scale, the discretionary power laid down in the Bill, which allows visiting committees to increase the amount of pension at their pleasure, is likely to find most favour with those concerned. The permissive principle has worked very well in the past, with few exceptions, and asylum officials, with the certainty of assured pensions in the future, will doubtless be content to trust to the sense of fairness and justice of the visiting committees to deal liberally by them.

The attitude of the Lord Chancellor towards the superannuation question is evidently sympathetic, and he emphasised the necessity of favourably considering the claims of a deserving class of public servants, both in their own interest and in the interest of the unfortunate individuals confided to their care. He attached great importance to the principle of the superannuation clauses and expressed the hope that

amendments would be moved in Committee to give the best possible shape to the proposal. This is as it should be, and it now rests with the Parliamentary Committee of the Medico-Psychological Association to press forward their views on the subject, on the lines formulated in the report published in the *Journal of Mental Science*, October, 1897. We hope that success will attend their efforts. The provisions made for granting allowance in the case of injury or death in discharge of duty is undoubtedly in the right direction. Reviewing the Bill as a whole we cannot say that it will tend to lighten the labours or lessen the responsibility of those engaged in the care and treatment of the insane.

THE advances which have been made in recent years in the surgery of the brain and of the bowel are perhaps the most striking manifestations of the modern progress of surgery, but improvements of at least equal importance have taken place in the methods of surgical treatment of the kidney. In THE LANCET of April 30th we published the last of the Hunterian Lectures on the Surgery of the Kidney which Mr. HENRY MORRIS has recently delivered at the Royal College of Surgeons of England, and everyone who has read these lectures must acknowledge the great importance of the subject with which they deal. Renal surgery is altogether modern. Abscesses in connexion with the kidney had been occasionally incised but only when they had so closely approached the surface that they were pointing and the surgeon was doubtless greatly surprised to find that he had operated on a kidney. In the same way, too, renal calculi may have been removed after incision of a presenting pyonephrosis. These cases, however, are not really worthy of being considered cases of renal surgery at all. Further, it is true that in the sixteenth century the practicability of nephrotomy was discussed, but no application of these theoretical possibilities was ever made.

In 1869 GUSTAV SIMON of Heidelberg removed a kidney from a woman with complete success. This is the first real operation on the kidney. The possibility of life continuing in the absence of one kidney had been amply demonstrated by experiments on animals, but SIMON'S success was needed to convince surgeons that the same fact was true as regards human beings. The simpler operation of nephrotomy was, however, the renal operation which met with the greatest recognition and it was performed in no small number of cases for the relief of pyonephrosis and in a few of these a stone was removed. It was, however, not then recognised that there was an earlier stage than pyonephrosis in which surgical interference might be of advantage. In 1880 Mr. MORRIS cut into the apparently healthy kidney of a young woman and removed from it an oxalate of lime calculus. This was indeed a notable advance; it showed most conclusively that a thick layer of renal tissue could be cut through without any fear of uncontrollable or even severe hæmorrhage and that a wound of the kidney substance healed readily and thoroughly. But it showed much more than this: it showed that it was absolutely unnecessary to wait until a renal calculus had led to the complete destruction of a kidney before attempting to remove it and that it was not only possible but safe to remove a stone from a kidney otherwise quite healthy. The example thus set has been largely followed and the results have fully justified this alteration in practice. In Mr. MORRIS'S own cases of nephrolithotomy only one death occurred in thirty-four operations. The effect of this change of practice has been great, and as a consequence the operation of nephrolithotomy has largely replaced the simpler but less satisfactory nephrotomy in all cases in which the patient has applied for treatment sufficiently early. Another operation, which has done less perhaps than nephrolithotomy in the way of saving life but quite as much in removing pain and discomfort, is nephropexy, or "nephrorrhaphy" as it is frequently called. A moveable kidney has but little tendency to shorten life, yet it leads often to much suffering and may entirely incapacitate for any exertion, and in many cases the relief resulting from nephropexy is great and lasting. The latest development of renal surgery is of especial interest. When a kidney has been exposed by an incision it is occasionally found that the disease with which it is affected is limited to one part of the organ, and in a few cases it has been found possible to remove with success the affected parts only and thus to preserve a portion of an organ which otherwise would have had to have been altogether sacrificed.

If the recent advances in the surgery of the kidney have surprised those accustomed to the old order of things the modern surgery of the ureter excites still more astonishment. Numerous operations are now performed on the ureter, a structure which was quite recently considered to be wholly beyond the possibility of surgical interference. The first and probably the most important operation performed was ureterotomy for calculus, and though the operation is still rare yet it has been done by several surgeons and stones have been successfully removed from all parts of the ureter, from the pelvis of the kidney to the opening into the bladder. Strictures of the ureter have been relieved by ureterotomy and in some cases a portion of the tube has been excised with results which fully justify the operation. Ureteral anastomosis and ureteral grafting have received much attention in consequence of the frequency with which the ureter is involved in the operation of vaginal hysterectomy. Formerly the only hope which could be held out to a patient suffering from a ureteral fistula after such an operation was nephrectomy, but ureteral anastomosis and grafting bid fair to replace entirely this severe procedure. A still more extensive operation on the ureter is excision. It is only called for in cases of widespread and persistent disease, but it has been successfully performed for tuberculosis and other conditions of the ureter. Another subject considered by Mr. MORRIS in his lectures was "obstructive anuria." It is very rarely indeed that both ureters are simultaneously or almost simultaneously blocked by calculi. In most cases one kidney has been destroyed or rendered functionally useless by a stone and then later when the other kidney has taken on the double duty it too has had its ureter blocked by the impaction of a renal calculus. The symptoms which follow are identical with those met with after experimental ligature of both ureters

in animals and usually the symptoms which are commonly called "uræmic" are absent. The patient survives a few days, perhaps as many as ten, and then dies. The fatal ending is inevitable unless the obstruction is removed. It has taken many years for it to be generally recognised that obstruction of the intestines cannot be cured by the lavish administration of purgatives and that the obstructing cause must be removed or the bowel opened above the obstruction. In the precisely analogous case of obstructive anuria diuretics and exercise are still only too often relied on for treatment and a patient is allowed to succumb when an operation would have saved him. It is true that the percentage of spontaneous removal of the obstruction is greater in the case of the ureter than in the case of the intestine, but the principles involved are the same and an operation should be performed as soon as the diagnosis is established. The lectures were illustrated by an elaborate set of tables of operations on the kidney which must prove of great value in the preparation of statistics on this subject.[1] As one of the leaders in this important branch of surgery Mr. MORRIS could not have chosen a fitter subject for the Hunterian Lectures than the surgery of the kidney and he is to be congratulated on the ability which he brought to bear upon his task.

THE long-standing controversy between the advocates of cremation on the one hand and of inhumation on the other was once more revived by a lengthy and important letter published in the *Times* of April 11th. It was written by Sir FRANCIS SEYMOUR HADEN, who is well known to be an earnest advocate of earth-to-earth burial, and so uncompromising an antagonist of cremation that in his opinion, as expressed in THE LANCET of Aug. 19th, 1894 (page 381), "as a measure of public safety it ought to be at once declared a misdemeanour." Holding such views, and not sympathising with those who may prefer that their mortal remains should be submitted to the swift decomposition of combustion rather than to the fauna and saprophytes of the cemetery, he undertook to prove that "inasmuch as cremation renders the identification of the cause of death impossible, its practice cannot fail to operate as a direct incentive to crime, especially such forms of crime as are difficult of detection without prolonged and repeated methods of investigation," in the course of which argument the tenets of the Cremation Society and of Sir HENRY THOMPSON, its principal champion, were criticised with much frankness. In answer to inquiries Dr. THOMAS STEVENSON of Guy's Hospital said that "though he could not recall without great labour all the cases he had met with he had yet not only discovered poison by their exhumation but had been able to prove by it the innocence of suspected persons." The experience of Mr. THOMAS BOND of Westminster Hospital has been to the effect that "though, like Dr. STEVENSON, he could not furnish particulars of every case he had met with he had yet been concerned in the course of a single year (1891) in no less than four such cases, all of them proving by exhumation murder by arsenic; that in the very next year (1892) he had been called upon to make two such exhumations, which proved that a double murder had been committed, a man in one of them having been shot at a certain distance from behind, and a woman, also in the back, but at close range; that on another occasion—and that quite recently—he had exhumed a body after two months' burial and found that death had been caused by an illegal operation; and that he had had a similar case since." Mr. BOND also referred to the case of DE TOURVILLE and said that he "had no doubt many persons skilled in the use of poisons would more frequently resort to them if it were not for the knowledge that they were liable to be handicapped by exhumation." After a reference to several of the familiar cases recorded in the text-books Sir F. SEYMOUR HADEN concludes as follows: "There is no stronger argument against cremation than the imputation of foul play which it has in its power to cast on innocent persons. It is impossible to conceive anything more deplorable than the position of one who, having cremated, say, his wife, is afterwards laid under the imputation of having murdered her! By what right do the half-dozen enthusiasts which compose the Council of the Cremation Society—depriving him as they do of all possibility of proving his innocence—place a fellow citizen in such a light? No wrong can be greater, no martyrdom worse!" Sir HENRY THOMPSON, thus challenged, replied in the *Times* of April 13th that his book "Modern Cremation," published a few years ago, would fully resolve all the doubts and difficulties which have perplexed Sir F. SEYMOUR HADEN. The 102 exhumations in the course of twenty years were arrived at as the result of an inquiry organised by Dr. DANFORD THOMAS who sent a series of questions to the 334 coroners in England and Wales and received replies from 317 of them, embracing all the important districts. From the data thus received it was estimated that the mean number of exhumations made in a year throughout England and Wales is only five, and less than one yearly for poison. Sir HENRY THOMPSON points out the very serious defects in our present laws as regards death certification and contrasts it with the methods observed throughout France and Germany and suggests the appointment of a "médecin-vérificateur." The conditions which have to be fulfilled before cremation can be performed according to the rules of the Cremation Society of England are very stringent; an application in writing must be made stating that it was the wish of the deceased to be cremated after death or that he entertained no objection thereto; and *two* certificates from duly qualified medical men, one at least of whom must have attended the deceased, are required relative to the cause of death. These the society obtains direct, and it is therefore necessary in making application for cremation to give the names and addresses of such medical men in full. These methods of guarding against the too hasty cremation of persons who have died from violence or poison are so well devised that a committee of the House of Commons, after considering them, reported that "with the precautions adopted in connexion with cremation, as carried out by the Cremation Society, there is little probability that cases of crime would escape detection."

Everyone will admit that scientific discussions between

[1] Table I. and summaries of Tables II. to XI. will be found at p. 1310 of our present issue.

distinguished representative men ought to be conducted with at least the externals of a calm and judicial spirit, for which reason we were glad to find from the *Times* of April 14th that Sir F. SEYMOUR HADEN acknowledges that his letter printed on April 11th was characterised by "over-directness of more than one of its utterances."

Annotations.

"Ne quid nimis."

THE PARIS EXHIBITION OF 1900.

THANKS to our Paris Correspondent we were enabled to publish in THE LANCET of April 30th some interesting particulars of the plans which have been formed for the adequate illustration of all the departments which concern medicine and the allied sciences. It will have been noticed that the scheme is a most complete one and it only requires the cordial coöperation of the countries concerned to ensure the presentment of an object lesson in all that pertains to the art of healing which will show the world at large how far and how wide has been the progress during the century which that exhibition will commemorate. We note with pleasure that it is proposed to group the exhibits according to their natural affinities rather than under the head of each country, but we recognise that it will be necessary for very careful discrimination to be shown lest a prominence be given to any one nation in departments of science to which its actual share does not entitle it. In respect to Great Britain and her dependencies we would point out that prompt steps should be taken to initiate an organisation which should have for its object the ordering of the arrangements for our adequate representation in this "World's Fair." Too often these exhibitions testify more to the isolated enterprise of commercial firms than to general improvements in the arts and sciences. What is required is not an exhibition of wares, but of genuine inventions and scientific instruments of the best and latest type. It might be well for one section to be devoted to a historical series which would give the visitor a *coup d'œil* across the century and show him when such and such an invention was launched on the world, and what modifications it has undergone in the years which have followed. Thus there would be presented a picture of evolution in human ingenuity and a great tribute to the master-minds that first conceived ideas which have borne so much fruit. But it is not in mechanical inventions alone that such a mode of exhibition of the results of scientific labour could be made manifest. The same method could be well applied in every department which has to do with the prevention of disease, the care of the sick, and the preservation of health. We need not again enumerate them, they are concisely classified in the article which we published in our issue of April 30th. Nor are the triumphs of medicine in the nineteenth century confined to any one nationality. France may claim the invention of the stethoscope, Germany that of the ophthalmoscope, and England the introduction of antiseptic surgery. In each land names of almost as high eminence as those of Laennec, Helmholtz, and Lister may be cited whose work has contributed to the amelioration of the ills against which the profession of medicine strives. If England has her Jenner, France has her Pasteur, and Germany has her Koch; and one of the most remarkable features of this exhibition should be to show how bacteriology took its rise and where it has assisted in the elucidation of the nature of diseases and enhanced our means for their prevention and treatment. In order, then, that our country may be fairly and fully represented in this great display we would urge the Commission over which H.R.H. the Prince of Wales presides to take steps to secure a thoroughly representative committee or committees to fill in the details of the scheme which the authorities in Paris have outlined. To this end there might in the first place be formed a large body of delegates from State institutions, hospitals, societies, colleges, and schools, out of which might be constituted the representative committees of each of the great medical sections which will be illustrated. We are most anxious that there should be some definite and responsible organisation of experts who would control and arrange the objects to be exhibited from this country. This is a matter which ought not to be suffered to depend solely upon the chance of individual enterprise, but to be effective it should be organised and to be organised it should, we think, have State recognition and receive the aid of the Treasury in carrying out its objects. What applies to medicine may apply also to other departments and our main purpose in raising the question thus early is to stimulate public opinion on the subject and to interest our Government in it. The meeting of the International Medical Congress and of the other local congresses in Paris during the Exhibition may facilitate the creation of—at least as regards our calling—an organisation such as we have hinted at. We only throw out the suggestion; it is for others in authority to acknowledge its utility and to take steps to carry it out.

THE COUNTESS OF DUFFERIN'S FUND.

A PERUSAL of the thirteenth annual report of this fund, that for the year 1897, produces a very favourable impression of the energy, capacity, and tact with which the National Association for Supplying Medical Aid to the Women of India has carried on its work. This, it will be remembered, is an undertaking by women on behalf of women. The report abounds in every descriptive detail relating to the subject of which it treats and like most statements of its kind it is fortified by a mass of appendices, which provide the reader with information on all that concerns the conduct of medical education and treatment as carried out in the schools and hospitals under the control of the association as well as in hospitals in the Native States. It is practically, therefore, a book of reference. A mere glance at its pages, however, will suffice to show that the aid in sickness provided by the association has been much and widely appreciated. Difficulties, indeed, have had to be faced, but they have not been met in vain. In spite of caste prejudice the education of native girls in medicine has progressed, though as yet slowly. The student-roll for the past year includes 89 Europeans and natives in training for a subordinate grade of "assistant surgeon," 108 for that of hospital assistant, and 95 for those of nurse and compounder. Every effort is being made to stimulate the zeal of provincial governments and native gentry in support of the work of education done by the association and these endeavours have not been unsuccessful. Turning to the more directly practical side of the subject we find that there are 180 hospital wards and dispensaries in operation throughout India, most of them governed by, or affiliated to, the association. The fully qualified lady practitioners number 33, and there are 70 "assistant surgeons" and 117 hospital assistants or practitioners of the third grade. A point of significant importance is the fact that women of the purdah class—i.e., inmates of zenanas—are availing themselves with increasing readiness of the aid afforded to them under the new system of medical treatment. The funds available for the needs of the association have so far been generally adequate to its requirements. In some districts, however, notably in the Bombay and Madras provinces, a

marked falling off attributable to the prevalence of famine in these districts has been observed. A gratifying feature in this connexion is the liberality exhibited by several native gentlemen.

A MEDICAL SPEECH ON ALCOHOL.

MR PEARCE GOULD has been making a speech to the National Temperance League on alcohol and the advantages of doing without it both in health and in the treatment of disease. It takes a strong man to say the strong things which Mr. Gould said on the subject, especially if he happens to be a medical man. No doubt, as Mr. Gould says, the use of alcohol in medical practice is nothing now compared to what it was twenty years ago, much more forty years ago, when Dr. Todd's influence and the reaction from the so-called antiphlogistic treatment were at their height. Public opinion has been enlightened by the evidence of leaders in medicine such as Dr. Parkes, Sir William Gull, Dr. Gairdner, Dr. Sanderson, and others, and medical men have dared to treat disease without alcohol or with only small quantities of it. There are physicians and surgeons of reputation and success who are so strong in their convictions that alcohol is of little use in the treatment of disease, that it destroys tissues, lessens the resistance to microbes, deranges functions, spoils temper, and shortens life, that they are ready to testify to this effect in public in company with redoubtable champions of the temperance cause like the Archbishop of Canterbury, Sir William Whi e (Chief Constructor of the Navy), and the Bishop of Derry, who have as much prejudice to contend against in their spheres as the medical man has in his. We recognise with pleasure the good done by such testimony as Mr. Gould's. Men whose record and authority in the profession are such as his have the courage of their opinions and their honest testimony will be respected even by those who do not go quite so far in discarding alcohol as an element of diet or as a medicine. On one point the profession is unanimous—that moderation in the use of alcohol must be observed unless certain mischief is to follow; the quantities which our forefathers regarded as moderate would now be thought capable of doing much harm.

RECENT RESEARCHES IN METEOROLOGY.

AT a meeting of the Meteorological Society on April 20th Major Herbert E Rawson, R E., read a paper on Anticyclonic Systems and their Movements, commencing with the statement that cyclones and anticyclones have long been recognised as powerful weather controls, but up to the present time very little has been written in this country upon the progressive movements of the cores of the permanent high-pressure areas which are found to be associated with certain localities at different times of the year. He has come to the conclusion that if the various anticyclonic systems are considered separately and their movements investigated continuously throughout the year their cores will be found to have a distinctly marked progressive motion and that the movement of a high-pressure system is to be gathered from that of its core, as plotted on a chart from month to month. The high-pressure areas of the globe may be divided into those of the northern and those of the southern hemisphere. In the latter a well-defined system is always found in the Pacific off the west coast of Chili; another is off the west coast of Cape Colony, and another is in the Indian Ocean to the west of Australia. In the northern hemisphere there is a system in the Pacific to the west of California which persists throughout the year; there is another over the Atlantic for about ten months of the year, and there are two over the United States and over Central Asia for about six months of the year. The movements of the anticyclonic systems in the northern hemisphere are more difficult to follow than those in the southern, but there is always a progressive movement in some direction or other and the law that high-pressure areas move off the land as temperature increases and return to it or form over it as temperature falls can be recognised. There is a definite progressive anticyclonic movement westwards from Siberia and Russia towards Great Britain in the early months of the year, and eastwards back again to Siberia in the later months. Major Rawson analysed at great length the results of plottings from various weather charts, especially Buchan's isobaric charts and those of the united Danish and German meteorological offices. One of his tables showed that from 1881 to 1891 the core of an anticyclonic system was over the British Isles on 212 occasions, 130 of which were due to the Atlantic system, 41 to the Scandinavian, 17 to the Greenland, 22 to the Atlantic and Scandinavian merged, and 2 to the Atlantic and Greenland merged. The indications are in favour of the idea that the atmospheric conditions over these islands foster the formation of an anticyclonic core, and the centre of the Atlantic system is displaced accordingly in that direction, but that the cores do not continue long in the neighbourhood, owing in the first instance to the ever-varying seasonal changes of temperature and next to those brought about by the general atmospheric circulation. These two influences appear to Major Rawson to be of supreme importance in determining the direction in which any anticyclonic system will move, and he considers that if further investigation should confirm his views the result would be a valuable addition to the present method of forecasting by means of synoptic charts.

THE SANITARY POWERS OF THE BRADFORD CORPORATION.

A VERY important case, both from the point of view of the property owner and of the public health authority, was heard on April 28th before the stipendiary magistrate at the Bradford city police-court. Proceedings were taken to recover penalties from an owner, Mr. Holdsworth, in Shuttleworth-lane for neglect to comply with a notice requiring him to convert certain privy accommodation into water-closets. Mr. F. Stevens, who appeared for the corporation, stated that the summons had been issued under Section 21 of the Bradford Improvement Act of 1873, the wording of which is as follows:—

"In addition to all powers vested in the corporation the corporation may in any case where a dwelling-house within the borough shall be without a privy, water-closet, or earth-closet, or an ashpit, or without a privy, water-closet, or earth-closet, or an ashpit of a construction and size approved by the corporation, require the owner of such house by notice under the hand of the mayor or town clerk for the time being, to provide such a privy, water-closet, or earth-closet, or such an ashpit, or to make such reparation or alteration of the existing privy, water-closet, or earth-closet, or ash-pit, as in such notice shall be stated and within a period to be therein mentioned. If such owner shall neglect to comply with such notice within the time therein appointed he shall for every such offence forfeit a sum not exceeding five pounds, and a further penalty not exceeding the like sum for every day during which such offence shall continue."

Briefly stated the facts of the case were these. On Nov. 23rd, 1897, Mr. Holdsworth's property was inspected by a sub-inspector of nuisances who reported that the privies and ashpits in six houses belonging to the defendant were in a foul and dilapidated condition. On Dec. 1st the matter was reported to the sanitary committee of the city council and they passed a resolution that the houses should be provided with water-closets and ashpits of the construction and style approved by the corporation. Due notice was served on Dec. 7th but nothing was done up to Feb. 15th, 1898. Notice was given of the intention to commence prosecution but still

the privies were there and on March 28th the summons was taken out. It was allowed by the prosecution that the privies had been repaired, but they contended that they were still privies and not water-closets. The property was originally built in 1873 under the supervision of a corporation official, but for the last five or six years the corporation had ceased to sanction the erection of new privies. The stipendiary magistrate reserved his decision for a week and judgment was finally given on May 9th. He found that the contention of the corporation was good in law and he fined the defendant 20*s*. and 8*s*. costs and said he would state a case for the consideration of the High Court. As far as we can see by the wording of the Act under which proceedings were taken the corporation does not seem to have the power to order the conversion of a privy into a water-closet. The Act only says that the corporation may require the owner to make such reparation or alteration of the existing privy as shall be stated when notice is given. It can hardly be said that the conversion of a privy into a water-closet is an alteration of an existing privy. The question which of the two systems is the better from a sanitary point of view does not seem to us to be the point at issue and it was allowed by the prosecution that the defendant had improved his privies; so that had they been in as good a condition when the case arose as they are now he would probably not have been troubled in the matter.

DEATH FROM "DIPPING."

AN inquiry was held at Aston on May 5th relative to the death of a man described as an annealer and dipper. His duty appears to have been that of dipping copper cups in dilute nitric acid after they had been annealed and pickled. The medical evidence pointed to acute congestion of the lungs, a condition consistent with the statement that the deceased had inhaled acid fumes. The jury returned a verdict in accordance with this and added that they did not attach any blame to anyone, but recommended the company to supply chemically charged respirators for the men employed in work similar to that which the deceased did and to have printed notices exhibited to that effect. The product of the action of dilute nitric acid on copper is, of course, nitric oxide, which, however, in contact with air forms nitric peroxide. This dark red fume meeting the moisture of the respiratory passages would split up into nitrous and nitric acids, which are distinctly injurious to the lung tissue. While agreeing with the verdict we think that some suggestion might have been made as to the possibility of substituting a mechanical dipping arrangement, so that the operator might avoid inhaling the fumes. The dipping process appears to be so simple as to imply the adoption of an equally simple mechanical contrivance.

THE PARALYSES OF WHOOPING-COUGH.

AT a time when whooping-cough is so prevalent a peculiar and practical interest attaches to a careful study by Dr. Charles Leroux of the paralyses associated with this disease. The results of his investigations have been published in several recent numbers of the *Journal de Clinique et de Thérapeutique Infantiles*—March 31st to April 28th, 1898. The total number of cases collected by him is 38 Of these 25 were those of children under five years of age. The paralytic seizure occurred in most cases during the ascendency of the disease but in some during its decline. It was associated with severe types and sometimes with various complications, such as scarlet fever, broncho-pneumonia, &c. Dr. Leroux classifies the resulting lesions under four chief headings. 1. Cerebral paralysis. This is commonly hemiplegia, though 2 cases of monoplegia, both of the right arm, are also recorded, as well as cases of aphasia and cases of disturbance of special senses. 2. Of spinal paralysis 2 cases with paraplegia of the legs are quoted. 3. There are also 4 cases which appear to depend upon peripheral disorders, different groups of muscles being involved in each case. 4. An example of disseminated sclerosis, though possibly existent before the cough began, appeared to be distinctly aggravated by its development. Dr. Leroux draws attention to the question of prognosis. He finds the mortality to be 6 cases out of the 38 and he directs attention to the fact that very young children are particularly liable not only to die but, where this result is prevented, to retain a degree of permanent paralysis. As the age of the child increases the prospect of complete recovery from a seizure improves. The pathology of these various conditions, though more or less obscure in many cases, is decipherable with tolerable clearness by the light obtained from a limited number of necropsies. It comprises congestions, hæmorrhages—submeningeal, meningeal and cerebral—and patches of inflammatory softening. In discussing this part of his subject Dr. Leroux notes the fact that the cough paroxysm alone does not account for the nerve paralyses, as these have occurred repeatedly during the decline of the disease. He is disposed rather to regard whooping-cough as exercising a damaging influence on the coats of blood-vessels in the nervous tissues, very much in the same way as other infections have been shown to do. Whether this theory be entirely justified or not it is at least instructive to be reminded of a complication which, though rare, has long been recognised among the less regular characteristics of whooping-cough. Its bearing on treatment is obvious. In this connexion much is apt to be left to nature, but the cases above mentioned ought to impress the fact that there is a very real purpose in the maintenance of effectual sedative measures. The common practice of exposing children out-of-doors in all weathers is much to be reprobated as tending to induce those pulmonary troubles which are liable to induce convulsions and thus easily lead to other and dangerous forms of brain disturbance.

THE USE OF GLYCERINATED VACCINE LYMPH IN CHICAGO.

THE Department of Health of the city of Chicago was the first sponsor in the United States for the use of glycerinated vaccine lymph in public vaccination and is concerned to note, we learn from the March report of Dr. Arthur Reynolds, the Commissioner of Health, that not all producers and vendors of such lymph seem to be familiar with the requirements necessary to secure, first, a pure and sterile lymph—i.e., a lymph free from pathogenic bacteria; and second, a potent lymph—i.e., a lymph which shall give not less than 90 per cent. of successful typical results in primary vaccinations. The Department has learned of these defects through the frequent solicitations of producers to have their respective products substituted for that already in use and the consequent examinations thus made necessary. "In the latest instance," says Dr. Reynolds, "the lymph, put up in a 'Sternberg bulb' with much painstaking, gave an abundant growth of white pus cocci on streak agar, demonstrating that it had not been exposed to the inhibitive action of the glycerine sufficiently long. Yet the package was stamped, '*Do not use after June 1st, 1898.*' ... On the other hand, a product submitted in February last was found sterile, not only as to bacteria, but almost so as to vaccinal value. Out of twenty tubes used only nine typical vaccinations were secured. There was no indication on the package as to the age of this lymph, but the experience of the Department warrants the belief that it was more than 120 days from the calf." Glycerinated vaccine is said by Dr. Reynolds to lose its potency after about 120 days,

so that the evil done in this latter case to public vaccination, if less serious than in the case of an infected vaccine, is still of serious moment. Vaccinators in America, as with us, find it exceedingly difficult to secure the consent of the parents to another attempt at vaccination after a failure and every effort should therefore be made to reduce the percentage of failures to the minimum by using only a potent as well as a pure vaccine. The use of pure reliable vaccine has made vaccination popular in Chicago to a most gratifying extent, we learn from Dr. Reynolds's report, and the present is a very good opportunity for us to lay stress on the fact. Our readers will find in Dr. Copeman's Milroy Lectures[1] full information upon vaccination by glycerinated calf lymph, but if the lymph is bad successful results cannot follow and cause for renewed agitation will be given.

THE MANSION HOUSE AND THE LONDON HOSPITAL.

THE Lord Mayor is going to make another departure from routine in giving a dinner on May 18th at the Mansion House with a view of advocating the claims of "London's largest hospital" situated in its poorest part. His Lordship deserves every support and encouragement in this use of his influence and hospitality. No man of any means who reflects for five minutes on the work of the London Hospital, by day and night, will lightly dismiss its claims to consideration or deny himself the pleasure of helping to avert such a catastrophe as the closure of wards from financial stress would be. These claims are not too often pressed unduly on the public, but once in five years or so special appeals have to be made. Such is the nature of the present occasion, and the chairman and committee of the hospital are to be congratulated on having a Lord Mayor in such practical sympathy with them. No use of comfortable or superfluous wealth would be more beneficent than such a response to the Lord Mayor's kind appeal as will secure the committee of the hospital against anxiety for the next five years. We venture to hope that many who cannot avail themselves of his lordship's hospitality will associate themselves with his kindness as regards this great object.

AUSTRALIAN MEDICINAL PLANTS.

A CORRESPONDENT in Australia writes:—"Australia is rich in plants reputed to possess medicinal virtues, although at present only a few have been utilised, and these but to a limited extent. In New South Wales such plants are abundant, many kinds being found in the immediate vicinity of Sydney, especially in the Parramatta district. Two little plants of the gentian family, plentiful enough in the spring, have proved highly efficacious in certain stages of dysentery. The common native raspberry, like other species of *Rubus*, possesses astringent properties which may one day secure it a place in the colonial pharmacopœia, which already includes the native sarsaparilla, although, notwithstanding the latter abounds in the neighbourhood of Sydney, the bulk of the sarsaparilla used by colonial chemists is imported. The country people frequently prepare an agreeable and wholesome tonic from the native plant, which costs nothing save the labour of collecting it. It is also known by the name of sweet tea or wild liquorice. There is also a native laurel allied to the sassafras of the pharmacopœia, which possesses medicinal properties as yet but little understood. The castor-oil plant not only yields the well-known oil, but the leaves have been successfully employed as a galactogogue. The thorn apple is used in asthma, the seeds when expressed and made into an ointment with lard being said to be useful for irritable ulcers, burns, and scalds. The medicinal virtues of the various kinds of eucalypti, or gum trees, have become universally recognised, but it is not so generally known that they are shared also by the different species of tea tree and wattle. The flowers of the native pittosphorum yield a jasmine-like scent by distillation; and the boronia and other rutaceous plants abound in volatile oils. The foregoing are only a few of the many Australian native plants known to possess medicinal properties, and their luxuriant abundance during the greater portion of the year, combined with the ease with which many species can be cultivated in suitable localities, will at some future date give them considerable industrial value."

THE "JOURNAL OF TROPICAL MEDICINE."

IT is proposed, if enough support can be obtained for the scheme, to publish in London a monthly journal dealing with the diseases of warm climates, to be devoted to the publication of papers on tropical diseases and to the discussion of subjects scientific and practical affecting the interests of medical men in tropical and subtropical climates. The annual subscription, including postage, is to be 17*s*. We wish the promoters success in their new venture. They deserve it, for there is no country which has such a large interest in the tropics and the diseases common to them as our own. Any communication addressed to the Editors, *Journal of Tropical Medicine*, Messrs. John Bale, Sons and Danielsson, 85 to 89, Great Titchfield-street, London, W., will receive attention. The editors are Mr. James Cantlie and Dr. W. J. Simpson.

"INQUIRY" AT THE LEEDS GENERAL INFIRMARY.

WE are informed that an inquiry into the circumstances and means of applicants for treatment at the Leeds General Infirmary is in operation. Such inquiries are apt to be superficial and of very little use. But our information leads us to hope that the inquiry at Leeds will be of a more satisfactory character. This is desirable in the interest of the poor as well as in that of the subscribers. Nothing will resuscitate the interest in hospital work and charity and increase the support of them so much as honest and thorough investigations of the sort which we have every reason to believe are taking place at Leeds. We shall look forward to a valuable contribution to the elucidation of this subject by the managers of an infirmary which has long held a leading place among such institutions.

THE REMUNERATION (?) OF POOR-LAW MEDICAL SERVICE.

THE *Daily Telegraph* of April 29th had a paragraph stating that the medical officer of health of Luton has lately been showing that out of a salary of £80 a year he has to supply 10,000 bottles of medicine yearly and that this works out at the rate of a fraction under 2*d*. per bottle, professional service included. The statement is almost incredible—quinine, iodide of potassium, cod-liver oil, *plus* brains, medical education past and continuous, and professional status, all for 2*d*. Much is said about cheap dispensaries, out-patient departments, medical aid association rates, and so on; but in the light of such calculations as those we are noticing we must regard Poor-law guardians—at least the guardians at Luton—as the worst sweaters of the profession. How can guardians expect the poor to be well treated or soon restored to health at such rates of payment? The only answer which can be made is that the guardians rely on the humanity of their medical officer instead of on the justice of their own arrangements. This has been too long the way of bodies having to determine the remuneration of medical men, especially of guardians. It is time that this should cease. The humanity of medical men is a large store on which to draw, but it has been terribly abused and in

[1] Lecture I. was published in THE LANCET of May 7th and Lecture II. will be found at p. 1303 of our present issue.

their own interests and that of the public such abuse should no longer be allowed. The profession is not free from blame for such beggarly treatment, and a little of the independence and self-assertion which have been shown in respect of the grievances of the Army Medical Department will have the same beneficial effect in the Poor-law medical service.

THE ROYAL COMMISSION ON THE DISPOSAL AND TREATMENT OF SEWAGE.

THE constitution of the Sewage Commission was announced by Mr. Chaplin in the House of Commons on May 5th. Public health is represented by Sir Richard Thorne Thorne, K.C.B., and Dr. James Burn Russell; biology by Professor Michael Foster, and chemistry by Professor Ramsey. The names of the rest of the Commission will not be so well known; they include two officers on the retired list of the army—namely, Major-General Constantine Phipps Carey and Colonel Thomas Walter Harding—and Mr. Charles Philip Cotton and Mr. Thomas William Killick. Though it must be regarded as a strong and representative board there is not included amongst its members, oddly enough, either a bacteriological expert or an expert on sewage engineering. The Earl of Iddesleigh is to be the chairman and Mr. F. J. Willis the secretary of the Commission. The scope of the inquiry is indicated in our Parliamentary Notes on another page.

THE TRUCK ACT, 1896.

A CORRESPONDENT draws our attention to the Truck Act of 1896 and suggests certain questions respecting its bearing upon sick funds where the collections for these purposes are made by employers or by their representatives. He asks whether it will affect the position of the surgeon, whether the doctor's fund comes under that Act, whether the employer must in future abstain from making the collection of the contributions of the workpeople, and whether the fund itself must be placed in the hands of the men. These are matters of great importance and if any doubt can arise about them it is certainly most desirable that it should be set at rest forthwith by the publication of an authoritative utterance. We have perused the Statute and we confess that it appears to us pretty clear that no one of these questions can arise. The Act relates, and relates only, to deductions from the workman's wages by way of fines and penalties or of payment for the supply of materials and tools. The position of medical funds and the conditions under which they can be collected by deductions from wages were regulated by a section (23) of the old Truck Act passed in the time of William IV. and they have remained upon that footing ever since. We are unable to discover in the new Act anything which disturbs that established position and we imagine that the questions formulated by our correspondent can be answered by a comprehensive "No."

THE DANGER OF ASPIRATING THE LIVER.

ASPIRATION of the liver is performed as an exploratory operation for suspected abscess; it has also been recommended as a means of blood-letting in certain diseases of that organ. The danger of this practice, which is far from generally known, is shown in an important paper published by Surgeon-Lieutenant-Colonel Hatch in the *Indian Medical Gazette*, April, 1898. Free and even fatal hæmorrhage from the enlarged and congested liver has resulted, and this effect seems more often to have been produced when no abscess was present than when one existed. The writer of the paper has had two fatal cases in his own practice and he quotes three others. He has no doubt that most Indian surgeons have had cases but unfortunately they have not published them as a warning. About three years ago two patients suspected of having abscess of the liver were aspirated by Surgeon-Major Quicke on consecutive days. In both the symptoms of internal hæmorrhage and death followed. A necropsy was made in one case; it showed blanching of the body and a large quantity of blood in the peritoneum and no abscess of the liver. But hepatic hæmorrhage was not the only cause of death. In a sixth case an intercostal artery was nicked and gradual hæmorrhage into an abscess cavity took place and proved fatal. Surgeon-Lieutenant-Colonel Hatch concludes that aspiration of the liver should never be performed as a mere means of diagnosis, but the facts might have carried him further, to recommend its total disuse. The operation offers no advantages to compensate for its undoubted risks.

INSPECTION OF VACCINATIONS.

UNDER the present system of arm-to-arm vaccination it is essential that the vaccinator shall see the child on the eighth day in order to maintain his supply of lymph. When the use of calf lymph comes to be the rule this will not be necessary and the date of inspection might be left more to the discretion of the vaccinator. In many cases more than one inspection might be made and wherever necessary more than one inspection ought to be made. Parents ought to be informed that if they so desire the vaccinator will revisit after his first inspection. This could easily be arranged by the vaccinator at the time of his inspection handing to the parent a form of request, perhaps printed on a postcard, for sending to the vaccinator asking for a later visit. The details would be for arrangement by local authorities and their officers and legislation is probably not required, but it would be well to know that power to make such arrangement exists, or may be provided for, under order by the Local Government Board or otherwise.

DIPHTHERITIC PNEUMONIA.

THE diphtheria bacillus does not always remain confined to the diseased mucous membrane but sometimes invades the blood and internal organs—the lungs, spleen, and lymphatic glands. Of these organs the lungs are most frequently affected; according to recent investigators, Kanthack and Stephens, in 26 fatal cases the bacilli were found with ease in all and in large numbers. In 15 of these cases broncho-pneumonia was present. What is the relation of the broncho-pneumonia to the bacilli? In almost all cases of broncho-pneumonia occurring in diphtheria other organisms such as streptococci and staphylococci are found in the lesions. It has therefore been supposed that the broncho-pneumonia is due to these organisms and not to the bacilli. Dr. S. Flexner and Dr. H. B. Anderson have published experiments in the *Johns Hopkins Hospital Bulletin*, April, 1898, however, which strongly support the view that the broncho-pneumonia is a truly diphtheritic lesion. They injected pure cultures of diphtheria bacilli into the tracheas of rabbits, which caused a definite and often widespread pneumonic process; but in certain cases, notwithstanding the entrance into the lungs of numerous bacilli, pneumonia failed to be produced. The pneumonia was lobular or pseudo-lobar in character and for the most part cellular, fibrin playing a relatively small part.

THE VENTILATION OF THE UNDERGROUND RAILWAY.

WE are quite in sympathy with those people who are protesting against the construction of more blowholes upon the Underground Railway. There can be little doubt that blowholes are a source of great inconvenience and discomfort to over-ground passengers and pedestrians, as well as to many residents, and it is an open question

whether they serve as a real remedy for the choky state of the tunnels. Yet a Select Committee of the House of Commons has decided to allow an increase of blowholes and a Bill has passed the House of Commons but not the House of Lords. The nuisance must exist as long as coal is used as a source of locomotive power. Mechanical ventilation has been suggested and this probably would be more effectual and satisfactory than blowholes which after all are merely openings in the tunnels, while the sulphurous smoke could be diverted by such means or even deprived of its impurities by forced passage over wet screens. Electrical traction is the ideal way out of the difficulty, but until that becomes universal we do not see the remotest prospect of its being applied to the Underground Railway, since there are other companies having running powers over its lines and though their trains are for a time passing through the underground tunnels they are more often travelling in the open air, so that smokeless engines are not an absolute necessity throughout the greater part of the journey.

A SIGN OF THROMBOSIS OF THE SUPERIOR LONGITUDINAL SINUS.

IN a recent number of the *Revue des Sciences Médicales* is an abstract of a case published by M. Lermoyez, who calls attention to a sign of great value in the diagnosis of thrombosis of the superior longitudinal sinus. A woman, aged thirty years, entered hospital for symptoms of septicæmia consecutive to old otorrhœa. There were severe pains in the temporo-occipital region. A hard cord was formed by the thrombosed jugular vein so that thrombophlebitis of the lateral sinus probably existed. Intervention was decided on; but the situation became aggravated and a new phenomenon appeared—dilatation of all the veins of the scalp without participation of the facial veins, which enabled M. Lermoyez to diagnose thrombosis of the superior longitudinal sinus. An operation was performed and an extradural abscess was evacuated, but the sinus thrombosis was too extensive for the removal of the clot entirely. The patient died comatose the following night. The necropsy confirmed the diagnosis.

THE VACCINATION BILL.

THE Vaccination Acts Amendment Bill was read a second time in the House of Commons on Monday last. The measure having a somewhat low position amongst the orders of the day the debate came on unexpectedly; it lasted over four hours and the division, taken at midnight, resulted in a majority in favour of the second reading of 214, only 23 votes being given against the motion in a House of 260 Members. The majority of the speeches were those of opponents to the Bill, such as Mr. Hazell, one of the members for Leicester, Mr. Channing, Mr. Labouchere (who spoke against it, but apparently voted for the second reading), Mr. Ashcroft (who brought a mandate from his constituency, Oldham, to oppose the measure), Mr. Whittaker of the Spen Valley Division of Yorks, Mr. Allan, and Dr. Clark. They chiefly argued against compulsory vaccination, but some more venturesome took the pronounced anti-vaccination position and maintained that small-pox could be as effectually dealt with apart from recourse to what they characterise as a method of more than doubtful efficacy. Dr. Clark, whilst expressing his personal belief in the modifying influence of vaccination over small-pox, seemed to arrive at a similar conclusion as to the method of dealing with the disease. The speeches in support of the measure by Sir C. Dalrymple—a member of the late Royal Commission—Mr. T. P. O'Connor, Dr. Farquharson, and Mr. T. W. Russell, the Parliamentary Secretary to the Local Government Board, were certainly better furnished with argument and doubtless influenced the division. In particular Mr. O'Connor's virile and pithy contribution to the debate put the case for vaccination in a nutshell. Mr. Chaplin's motion to refer the Bill to the Standing Committee on Law was strenuously opposed mainly on the ground that its controversial character required its discussion in committee of the whole House. Mr. Chaplin, however, carried his motion by a majority of 151—201 voting for and 50 against it.

PULEX IRRITANS.

A CORRESPONDENT has written to us to know the best way of exterminating the flea pest. As the season is approaching when pulex irritans makes its presence most felt the following summary of some remarks and correspondence which appeared in THE LANCET in 1895 [1] may be useful. Thorough and systematic cleaning is, of course, a first principle in the plan of prevention. The use of common English lavender kept with clothes or in beds has been tried with good results. Paraffin is said to act similarly but its smell is disagreeable. If before retiring for the night the body be sponged with weak vinegar and water pulex irritans will often cease from troubling. The irritation caused by the bite may generally be allayed by the application of sal volatile or salt and water. Strong infusion of quassia freely used as a wash is said to cause swarms of fleas to vanish "as by magic." A little chloroform poured on the clothes over the point of attack soaks through and permanently quiets pulex irritans and allays the irritation of its bite. It is curious to remark the preference which the pest appears to evince for certain persons and, again, while some persons are extremely sensitive to its bites, enormous wheals being raised, others are merely annoyed by its peregrinations over the body.

THE PERILS OF A SANITARY INSPECTOR.

AN Englishman's house is no longer his castle in these democratic days. That comfortable doctrine is almost as dead as the belief in the Divine right of kings, and a case which recently came up at the Liverpool police-court is a good example. Hugh McCarthy, a dock labourer, was charged with assaulting Ethel Frances Burton, a sanitary inspector under the corporation. Miss Burton arrived in uniform to inspect the defendant's house and was promptly tackled by Mrs. McCarthy, who took her into an adjoining room where Mr. McCarthy was lying on a sofa. He and his wife then detained Miss Burton for the space of an hour, in the meantime examining her books to see what names were entered therein. Ultimately she was liberated at the request of one of the children. The defendant pleaded that he "had just had some words with his wife," but he was fined 20*s*. and costs. Everyone will remember that inimitable scene in "Bleak House" where Mrs. Pardiggle and the children who were members of the "Infants' Bond of Joy" visited the recalcitrant bricklayer, and had Miss Burton been a person of the Pardiggle type we should have sympathised with Mr. McCarthy, but official sanitary inspectors stand upon a very different footing. They fill a most useful part in our modern economy and at all risks must be protected against interference with their duty.

MILK PRODUCTION UNDER SCIENTIFIC CONTROL.

NOTHING could be more satisfactory than the increased attention and care now being bestowed by large dairy companies to secure the production of healthy milk. Bacteriology has from its infancy indicated the necessity of scientific control in this industry, and it is satisfactory and reassuring to know that its teachings are not ignored. Again, most large producers find it necessary in view of the advance of public education to be prepared to provide milk of definite

[1] THE LANCET, April 6th (p. 882) and 20th (p. 1018) and May 4th p. 1163), 1895.

composition for infants and invalids. Thus, to take one example, we have before us a synopsis of the appointments, equipments, and products of the dairy managed by Messrs. Welford and Sons. The staff includes medical officers, sanitary inspectors, veterinary surgeons, and an analyst. The preparations include facsimile human milk, peptonised milk, sterilised milk, sweet whey, sterilised cream, sterilised separated milk, butter milk, koumiss, asses' milk, and milk for the nursery. In addition to the steps which are taken to ensure the supply of nothing but healthy milk samples are also taken every day and analysed in the laboratory, all milk falling short of a standard quality being rejected. The procedure thus adopted by this important branch of industry might well be followed in other branches, and it is a tribute to the constant representations of bacteriological investigators that commercial enterprise has acted upon scientific teaching and has admitted the necessity of scientific control. By such a forward step the community at large gains not a little.

MEDICAL GUESTS AT THE SAVAGE CLUB.

THE members of the Savage Club have lost no time in following the admirable example set by the Lord Mayor of London in entertaining the medical profession, or at all events certain representative members of it, at dinner. Recently, we understand (and for this information we are indebted to our contemporary, the *Medical Press and Circular*), the Lord Chancellor and other distinguished members of the legal profession were present at one of the customary Saturday evening dinners of the Savage Club. This seems to have suggested to some of the members of that interesting body the happy thought of extending similar hospitality to the sister profession of medicine, and the occasion of the occupancy of the chair on Saturday last by Mr. J. Y. W. MacAlister, who, as the esteemed Librarian of the Royal Medical and Chirurgical Society, is closely associated with our profession, was evidently thought to be—as indeed it was—very appropriate to the purpose. Among the chairman's guests were Sir Samuel Wilks, President of the Royal College of Physicians of London, Sir William Mac Cormac, President of the Royal College of Surgeons of England, Sir Dyce Duckworth, Mr. Bryant, Dr. Ferrier, Dr. Church, Mr. Warrington Haward, Dr. C. J. Hare, and Mr. Thomas Wakley, Jun. Among other medical guests present were Dr. George Ogilvie, Dr. Danford Thomas, and Dr. Aldren Turner. The Savage Club has quite a fair sprinkling of medical members, amongst those present on this occasion being Dr. Abraham, Dr. Symons Eccles, Dr. Sims Woodhead, Mr. Percy Dunn, Dr. Strahan, and Dr. Gubb. That the room was full is certain; that the songs, recitations and other forms of entertainment—not forgetting a "really wonderful" (the clever performer's own description is certainly applicable) card trick—were of the very best quality is also certain; the pleasure of the medical visitors, moreover, was probably not lessened by the fact that after-dinner speeches seem to be "taboo" at the Savage Club. The only touch of local—i.e., medical—colour was an interesting Roentgen Ray demonstration by Dr. F. Low. Last week we thanked the Lord Mayor; this week we tender our thanks to the members of the Savage Club, not only for hospitality, but for the kindly thought which prompted it.

A MEETING of Convocation of the University of London was held on May 10th. The chief business was the re-election of the chairman and clerk of convocation, a motion of the Standing Committee to alter the date of the autumn meeting to the *second* Tuesday in October, and the appointment of members of the Standing Committee.

H.R.H. THE PRINCE OF WALES, who is a Vice-patron of the institution, has consented to lay the foundation stone, on Tuesday, June 21st, of the extension of the University College Hospital Buildings now in course of construction through the generosity of Sir J. Blundell Maple, M.P.

HER MAJESTY THE QUEEN has been graciously pleased to sanction the following appointments to the Order of the Hospital of St. John of Jerusalem in England: Knights of Grace: Sir Richard D. Powell, Bart., M.D. Lond., and Mr. William Hamerton Jalland, F.R.C.S. Eng.

SOME disappointment was felt at the Royal Society's conversazione on Wednesday last that Professor Dewar's recently announced achievements were not demonstrated. It is stated that he has succeeded in liquefying helion as well as hydrogen in fair quantity.

H.R.H. THE PRINCE OF WALES has fixed Wednesday, June 8th, at the Hotel Cecil, for the dinner at which he has graciously consented to preside on behalf of the National Society for the Prevention of Cruelty to Children.

THE IRISH LOCAL GOVERNMENT BILL.

I.

THE introduction of the Irish Local Government Bill, which will no doubt speedily pass into law, marks an important epoch in the history of the sister island. An attempt is being made to introduce into that country those principles and methods of democratic government in rural districts which have already been tried in England and Scotland with, on the whole, satisfactory and encouraging results. However critics may find fault with the county councils and however much the action and policy of some of those councils may have left them open to censure no one doubts that the establishment of such engines of government was an inevitable step in the onward progress of democracy and no one dreams that this step should be or could be retraced. Rural government having thus been put upon a broad popular basis in England and Scotland it was only a question of time and of a short time until similar methods should be applied to Ireland. The circumstances of the sister island are no doubt in many respects exceptional and in not a few painful and difficult, but the political instinct of the British people, which has rarely been in fault in the past, has rightly suggested that a bold effort should be made to extend to Ireland the boon of popular government in rural districts. There is a general conviction among men of the most different political opinions that the attempt is just and wise—one which must of necessity be made and one which, even if attended by some temporary dangers and inconveniences, would, as Mr. Gerald Balfour said in introducing his Bill into the House of Commons, ultimately "work through failure to success." This may be said without implying any serious censure upon the present methods of local government in Ireland. No one who knows the country and who is free from political prejudice can assert that the grand juries have been either generally inefficient or extravagant or corrupt. They are composed for the most part of the leading land proprietors in the different counties, summoned nominally by authority of the High Sheriff, but really owing their position to long prescriptive right, and their discharge of their duties has been on the whole such as might have been expected from the Irish gentry—i.e., it has been well-meaning, absolutely free from all financial corruption, and in some counties singularly efficient; but in other cases it has been slack, inefficient, and unprogressive. The grand jury system, however, stands condemned not because of any gross abuses or admitted inefficiency, but because its whole basis was illogical, one-sided, oligarchical, and entirely out of touch with the tendencies of a democratic age. It

was class government and government by a class which had managed to render itself profoundly unpopular in Ireland. As Mr. Gerald Balfour truly said, "the grand jury system has no principle of growth in it. The tendency of the present day is to throw upon local bodies a number of duties which were never considered in connexion with local administration a generation ago. You cannot put new wine into old bottles and reform of local government has become almost a condition of certain further reforms."

If the necessity for reform in local administration in Ireland be conceded, no one will deny that the present time is a singularly favourable one for passing a thorough and satisfactory measure. In these columns we take no account of party questions, but it must be evident to anyone who has followed the trend of recent politics that the present Conservative and Unionist Government is exceptionally fortunate in bringing forward a first-class Irish measure at a time when men of all shades of political opinion are prepared to give it a candid and sympathetic hearing. That irreconcilable attitude towards reform which has wrought such havoc in other countries and which has before now obstructed progress in Irish affairs seems for the present to have been abandoned by the various Irish parties, who are apparently united in their admission of the necessity for reform and their desire to make that reform thorough, consistent, consonant with the tendencies of a democratic age, and such as will hold out some reasonable prospect of permanence. This unanimity is encouraging and is of good augury for the future of the country.

The measure now before the House of Commons aims at applying to Ireland those general principles of local administration which are already at work in England and Scotland, but with certain modifications which are rendered necessary and expedient by the special circumstances of the sister island. The Scotch system differs in certain particulars from the English. The Irish will differ from both the Scotch and the English. Thus, "in England," as Mr. Balfour said, "we have county councils, district councils, and parish councils. In Scotland we have only county councils and parish councils. ..... In Ireland it is not proposed to establish parish councils. The parish has never been in Ireland an area of local administration, and to create parish councils there would merely be to add a superfluous complication to our scheme. We propose that local administration in Ireland should be distributed between county councils, urban district councils, rural district councils, and boards of guardians. ..... This fourfold division will, however, in the majority of cases be practically reduced to a threefold division, inasmuch as any person who is elected a member of a rural district council will represent the area for which he is elected not only as a district councillor, but also as a guardian, and where the union is wholly confined within the administrative county the union will be coincident with the rural district and the board of guardians will be the rural district council under another name." The county councils will take over the functions at present exercised by the grand juries and presentment sessions of counties, and the rural district councils will take over the powers of the baronial presentment sessions. Any proposed expenditure on roads or other public works payable by the rural district council will be referred by that council to the county council, which may approve or disapprove. If it approves, the work will be carried out by the county surveyor, under the direction of the county council. The county council will also be the sole rate-collecting authority in rural districts. In order to provide a link between the rural district councils and the county councils it is arranged that the chairmen of all rural district councils shall be *ex-officio* members of the corresponding county council. The franchise will in all cases be the existing Parliamentary franchise, with the additional provision that peers and women shall possess votes. Ministers of religion of all denominations are precluded from sitting upon any of the councils. This is a provision which is sure to give rise to much difference of opinion, but the preponderance of view will probably be found to be in favour of the proposal of the Government. The transfer of grand jury powers to county councils will be limited to the fiscal and administrative powers of the grand jury and will not extend to their present criminal jurisdiction or their powers in relation to compensation for malicious injuries. The present Board of Control exercising control over lunatic asylums will be abolished and the appointment by the Lord-Lieutenant of boards of governors and of officers of asylums will cease. "It will hereafter be the statutory duty of county councils to provide and maintain sufficient accommodation for the lunatic poor in the county and to manage the lunatic asylum. For this purpose they will act through a committee of the council, or where an asylum district comprises more than one county through a joint committee, in which each council will be represented in proportion to the expenditure which it has to defray in connexion with the asylum. One-fourth of the members of a committee may be appointed from persons other than county councillors." The appointment and removal of the officers of asylums will rest with the county council, acting through their committee, but the concurrence of the Lord-Lieutenant will be required in the case of a resident medical superintendent and of the assistant medical officer. To this provision, which is so important to the medical profession, we shall subsequently return. As regards the methods of dealing with cases of exceptional distress, unfortunately not an unusual condition of things in Ireland, the Bill provides that when a board of guardians considers a state of exceptional distress to exist within its union requiring relaxation of the conditions of outdoor relief they may apply to the county council. If the county council thinks that the circumstances justify the application they may request the Local Government Board to issue an order authorising the guardians, subject to the prescribed conditions, to administer relief outside the workhouse for a limited time from the date of the order to poor persons of any description resident in the distressed area. If the Local Government Board issues such an order the county will become liable for one-half of the extra expenditure incurred by the board of guardians in administering this special form of relief. These provisions are intended to obviate the necessity for passing a special Act of Parliament each time that such cases arise. The rural district councils will assume the powers and duties of the existing rural sanitary authorities. The county electoral divisions are to be fixed by the Local Government Board. Six towns and cities will be constituted county boroughs—viz., Dublin, Belfast, Cork, Limerick, Londonderry, and Waterford. The government of these boroughs will go on as before except that their councils will be elected on the Parliamentary franchise and they will obtain such powers and duties of county councils generally as they do not already possess. In the case of other towns and boroughs every place which is now or shall become an urban sanitary district will be an urban district under the Bill and its affairs will be administered by an urban district council. All urban district councils shall be the road authority for their district. The urban district councils will have the duty of levying and collecting all rates within their district. *Ex officio* Poor-law guardians are to be abolished. This was an inevitable concession to democratic ideas, although it cannot be truly said that *ex-officio* guardians abused their privileges or contributed an objectionable element to these boards. Their retention was, however, manifestly impossible. The duties hitherto allotted to the guardians as rural sanitary authority will be transferred to the district councillors. The duty of levying and collecting the poor-rate will be transferred in rural areas to the county council and in urban areas to the urban council. Dispensary committees will be abolished and their functions transferred to guardians.

The financial arrangements under the Bill are bold, novel, and ingenious. Their originality, simplicity, and the generous consideration which they show for the special exigencies of Ireland are worthy of hearty recognition, and no doubt have had much to do with the generally favourable reception which the Bill has received. The occupier is to be in future liable for both the county cess and the poor-rate, whether in towns or in rural districts. The distinction between cess and poor-rate will cease, and the two will be collected together as one consolidated rate. In readjustments of rent the financial year 1896-97 is to be taken as the standard and all adjustment of rent is to be made on the assumption that there will be no increase or decrease of poor-rate and county cess taken together as compared with the total rate in the pound for county cess and poor-rate taken together in the standard year. This arrangement secures that any decrease in the rates will go to the benefit of the occupier while any increase will go to his disadvantage. The Bill provides that there shall be distributed for the benefit of the spending authorities in each year out of the Imperial Exchequer a sum equal to one-half of the county cess and one-half of the poor-rate deemed for the purposes of

the Bill to have been paid in respect of agricultural land in the standard year. This sum is to be called "the agricultural grant." Provisions are inserted in the Bill to secure that the benefit of this contribution shall go to the occupier as regards county cess and to the owner as regards poor-rate. The general tendency of these provisions will be, on the one hand, to prevent the landlord having his rents lowered in consequence of any rise in the rates and, on the other hand, to secure the tenant from having his rent raised in consequence of the relief in respect of county cess given by the agricultural grant. When the occupier of the land is also the owner he will get a double advantage out of the grant: as occupier he will get relief in respect of county cess; as owner he will get relief in respect of poor-rate. The Bill provides for union rating and district rating. As regards the former those expenses of the guardians which are now levied separately on an electoral division will be charged on a common fund raised equally over the whole union. As regards the latter the cost of roads and public works, instead of being charged specially to particular baronies, will be charged equally over the whole of the rural district, which will in most cases comprise several baronies or parts of baronies. Each of these changes will have the effect of shifting burdens, lightening them in some quarters and increasing them in others. They must, therefore, be taken into account in calculating temporary adjustments of rent as between landlord and tenant and also the amount and distribution of the agricultural grant. The effect of these provisions will be to increase the agricultural grant by £11,000 or £12,000. The total amount of this grant is reckoned at about £730,000 annually. Certain charges will be excluded—viz., charges for extra police and compensation for criminal injuries, charges in respect of railways, harbours, navigation, and special expenses under the Public Health Acts. These charges are not to be taken into account by the Land Commission in fixing fair rents. It is proposed to follow in Ireland the precedent set by the English Act of 1888 whereby the proceeds of local licence duties were transferred to the local authorities in lieu of certain annual Parliamentary grants. In Ireland the proceeds of the local licences amount to about £200,000, whereas the grants in respect of the maintenance of lunatics and certain Poor-law charges which it is proposed should be no longer paid amount to £244,000. This deficiency it is proposed to cover, and more than cover, by adding to the proceeds of the local licences a fixed annual grant from the Exchequer of £79,000. Out of the total of £279,000 thus made up it is proposed to defray the charges now met out of the grants in aid and the following additional charges: first, one half of the salary for one trained nurse in every union in Ireland if actually employed and possessing the prescribed qualification; and, secondly, where the aggegate rate levied in any year in order to meet the amount of any existing railway or harbour charge in any area exceeds 6*d.* in the pound a sum equal to one half of such excess. An increase in the lunacy charges is expected in consequence of the contemplated transference to asylums of the lunatic poor at present in workhouses.

It is proposed that the grand juries shall meet for the transaction of fiscal and administrative business for the last time at the spring assizes of 1899. The elections for the new bodies will follow immediately afterwards in March. The interests of existing officers have been protected in various ways. Generally speaking, existing officers will either be retained or have the option of retiring with the same allowance as if their office were abolished. The existing county surveyors will not be removable except with the concurrence of the Local Government Board. All new appointments will, of course, be in the hands of the county council. As regards many formal and non-contentious matters power is given to the Lord-Lieutenant in Council to deal with such matters by means of adaptation and regulation orders. These orders must be laid upon the table of both Houses of Parliament and it will be open to either House to object to them in the usual way by an address to Her Majesty.

In the above outline of this very important measure we have closely followed the lines laid down by Mr. Gerald Balfour in his speech introducing it into the House of Commons. In a future article we shall deal more in detail with some of the provisions, especially those affecting the interests and position of the medical profession. There can be no doubt that the Bill is a broad democratic measure conferring great popular benefits and not weighted by any arbitrary or irritating safeguards. The lines of the corresponding English and Scotch measures have been followed, but not in any mechanical or slavish way, and due regard has been paid to the special circumstances of Ireland. There can hardly be any second opinion regarding the generosity and ingenuity of the financial regulations. They aim at conferring substantial pecuniary benefit upon a poor country, at restraining extravagance, and at giving the elective bodies the full benefit of any economy which they may exercise. All distinction of interest between one class of ratepayers and another is, as far as possible, obliterated. Much will depend upon the spirit in which the Act is received and administered. At present the omens are favourable. There is little active opposition to the Bill in any quarter. Some of the Irish Unionists regard it with apprehension, but others, to their great credit, heartily welcome it not only as inevitable but as likely in the long run to confer great practical benefits. The results are in the hands of the people, who may make serious mistakes but who are sure in the end to discover where their true interests lie. It is to be hoped that the gentry, whose existing privileges are to a large extent swept away by the Bill, will accept the new *régime* and seek their natural position as leaders of the people in the elective bodies about to be constituted.

LOCAL GOVERNMENT (IRELAND) BILL: MEMORIAL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following is the memorial presented by the Royal College of Surgeons in Ireland to the Chief Secretary for Ireland in respect of the Local Government (Ireland) Bill:—

To the Right Honourable the Chief Secretary for Ireland.

THE MEMORIAL OF THE PRESIDENT, VICE-PRESIDENT, AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

Showeth:—That your memorialists have considered the provisions of the Local Government (Ireland) Bill, so far as they affect the Fellows and Licentiates of this College and the medical profession generally and they respectfully submit for your consideration the following expression of their opinion thereon:—

1. The College regards the existing system of election of poor-law medical being also sanitary officers as very unsatisfactory, inasmuch as it has the effect of giving, and, in fact, has given, predominance in the election of such officers to considerations other than the competency of candidates for office and the necessities of the sick poor. The College, without desiring to deprive the local authorities of their legitimate influence in the selection of medical officers, considers that it should not be open to guardians or dispensary committees to place in charge of the sick poor persons who may be entirely inexperienced and whose competency for the special duties confided to them may be entirely unguaranteed. The College, therefore, submits that all candidates for such appointments should be subjected to a previous competitive examination in which a knowledge of their special duty as medical officers, as sanitary officers, and as public vaccinators could be verified.

2. The College is strongly of opinion that in this Bill adequate provision should be made to enable Poor-law medical officers to retire upon a pension as of right, if incapacitated from duty by ill-health, or upon abolition of their offices, or after completion of the period of service required from Civil servants. The College begs to remind you that the unlimited discretion vested in guardians by the existing law has in numerous cases inflicted extreme hardship on worn-out medical officers and has had the effect of retaining such officers in their appointments long after they had ceased to be capable of efficient duty to the great disadvantage of the sick poor of their districts. The College urges that inasmuch as medical officers have been recognised by Parliament as entitled to pension and have been placed by the Local Government Board in the position of Civil servants in regard to the amount of that pension it is but right that they shall be treated in all respects as Civil servants in this matter.

3. The College submits that the occasion afforded by this Bill should be availed of to improve the sanitary service in Ireland by providing adequate supervision by superintendent

medical officers of health. It must be evident that the system of relegating the sanitation of a district to a dispensary medical officer, uncontrolled by any superior officer and altogether dependent on local guardians, has had the effect in very many instances of rendering nugatory the law provided by Parliament, and the College is of opinion that no improvement in the existing condition of things can be hoped for until a supervising medical officer devoting his whole time to his function shall be provided to superintend the sanitation of the group of districts committed to his care.

4. The College is of opinion that it is indispensable to the efficiency of the future administration of district lunatic asylums in Ireland that the experience and competency of future resident medical superintendents and assistant medical officers should be guaranteed by requiring as a qualification for these offices a sufficient proof of previous service in a public asylum, together with such other safeguard as may be deemed necessary.

5 That the College, having already addressed you on the subject of the future administration of county infirmaries in Ireland, refrains from further reference to the subject.

Your memorialists, therefore, earnestly request you to avail yourself of the opportunity afforded by this Bill to reorganise in regard to the subjects above referred to the public medical service of this country.

(Signed)
WILLIAM THOMSON, Knt., President.
ROBERT L. SWAN, F.R.C.S., Vice-President.
CHARLES A. CAMERON, Kt., F.R.C.S., Secretary of the College.
ROBERT H. WOODS, F.R.C.S., Secretary of Council.

LEAD POISONING IN POTTERIES.

IN answer to the question which Mr. Coghill put to the Home Secretary in the House of Commons on April 22nd as to whether, to prevent the serious evils arising from the use of lead in the manufacture of china and earthenware, he would appoint a small committee of scientific experts to ascertain if it were possible to use a glaze which would be entirely free from lead in its composition, the Home Secretary replied that he was taking steps to secure the services of two eminent scientific experts to test and report on the various glazes, but it must be clearly understood that the inquiry could deal only with the question of the comparative danger or safety of different materials. The further question how far materials found to be harmless, or relatively harmless, lent themselves to the practical requirements of each section of the trade, was one for the manufacturers to decide by experiment. He felt sure that he might count on their coöperation in this matter and their readiness to adopt satisfactory substitutes, if such should be found, for the dangerous glazes now in use.

We were under the impression that the subject had been fully inquired into by a thoroughly competent committee some years ago. And our impression is not wrong. We have before us a copy of a "Report to Her Majesty's Principal Secretary of State for the Home Department on the Conditions of Labour in Potteries, the Injurious Effects upon the Health of the Workpeople, and the Proposed Remedies." The report is dated July, 1893, and was presented to Mr. Asquith, the Home Secretary at that time. The members of the committee were as follows:—S. W. May (Superintending Inspector of Factories), chairman; J. T. Arlidge, M.D., F.R.C.P. Lond., W. D. Spanton, F.R.C.S. Edin., A. P. Laurie, M.A., B.Sc., F.R.S.E., J. H. Walmsley (H.M. Inspector of Factories); and W. Dawkins Cramp (H.M. Superintending Inspector of Factories), secretary. We may briefly abstract their findings and observations.

1. The proposal to substitute leadless glazes must be deemed impracticable after a careful consideration of the evidence.

2. The proposal that all the lead required in the glaze should be first fused (with borax, silica, &c.) and only this "fritted lead" be used in the glaze was worthy of careful examination, especially as the process seemed to involve no very great alteration in the present methods of manufacture.

3. Some firms are now fritting all their lead and claim that it is an improvement on the older methods; others do not regard it as practicable. The fact, however, that more than one important firm is using it for all classes of work shows that it is reasonable to suppose that the fritting of lead might ultimately be found universally practicable.

4. Mr. A. P. Laurie carried out some important experiments with a view of determining the solubility of fritts in weak hydrochloric acid. He found that all the fritts were much better than raw lead, being much less soluble in weak acid and therefore less dangerous to introduce into the stomach.

5. The committee recommended (we repeat that this was nearly five years ago) that steps should be taken by circular from the Home Office or otherwise to bring before manufacturers the advisability of experimenting with and testing the use of glazes and colours in which all the lead has been fritted and their effects upon the health of the workpeople; also that the committee should be empowered to continue investigations as to the composition of glazes and colours with a view of finding out how far it is practicable to make a glaze which shall be harmless to those employed in the manufacture and at the same time shall not injure the ware.

6. The following are quotations from the evidence of practical men and representatives of large potteries. "Fritted lead is as consistent with practical pottery as using the lead in the raw state." "The fritted lead is an easier flux than raw lead." "The workmen have no proof that fritted lead is non-poisonous, but believe it to be so." "Fritted lead can be used universally without injury to the trade, it does better for colours, and increases the brilliancy of the ware." "He never knew" (this came from a witness employed by one of the largest pottery firms) "of a single case of lead poisoning where all the lead was fritted." "Fritted glaze is better for coloured and printed ware as well as for white ware. Colours used in a glaze which has been fritted are not altered. Even the turquoise blue over glaze is fritted and the colour is not affected." The managing director of the same firm said that it would be advantageous to the manufacturers to fritt all the lead before use. When he found that fritted lead was being used for majolica and ornamental ware and that there had not been a case of lead poisoning in the department he turned his attention to the matter. Lead must be used. He found fritted lead was quite satisfactory for glazing both for china and earthenware. The ware is more brilliant and even with constant rough usage he had not observed a piece yet "crazed." He did not think a rule prohibiting the use of raw lead would injure any manufacturer. A district surgeon stated before the committee that at a majolica works in Burslem they use fritted glaze or colour and the health of the workers is good. In a letter placed before the committee two German manufacturers, after referring to the law in Germany, quoted an instance of having to pay a dipper who was affected by the lead and who lost the use of his eyes. They concluded: "We used to use our raw white lead in the glaze, but after the experience we had we now fritt it all." Two English manufacturers wrote: "There is not the slightest doubt that the lead is far less dangerous to the workpeople when vitrified. Nevertheless it is dangerous and all enamel makers have to contend with illness through lead poisoning although no free lead is used. The fact is the acids of the stomach do dissolve glass made from lead. We beg to state that we incline to the opinion of the workpeople you mention, that if the oxide of lead contained in the glaze is fritted before being ground for use the danger of lead poisoning is greatly minimised if not entirely avoided."

Against these statements there is the evidence of three English firms, manufacturers of china and earthenware. The following are extracts from their statement: "Any interference with the amount of free lead in glazes would mean absolute closing of one branch of our manufacture in which we have again and again tried to use fritted lead without success, and it would seriously cripple other branches"; "We have tried the plan of fritting the entire glaze, but without success so far"; "We have experimented for years with glazes but have not succeeded in dispensing with lead in its raw state; when fritted the character is so altered that we have failed to successfully work at it." Another firm wrote: "We have, however, made many experiments of fritted lead, &c., which are certainly encouraging and invite further effort."

Surely the Home Secretary could not have been aware of this inquiry and the unmistakeable trend of its conclusions when he gave the answer that he was taking steps, &c., to

have various glazes tested and reported upon and that he trusted he might count on the cöoperation of the manufacturers in this matter and their readiness to adopt satisfactory substitutes, if such should be found, for the dangerous glazes now in use. Surely the remedy was long ago indicated in the terms of this report which was drawn up after careful investigation nearly five years ago. We earnestly commend these facts to the Home Secretary and trust that in the name of humanity he will take steps to minimise as far as this report indicates it possible the grave liabilities to which the workpeople in potteries are exposed and of which quite recently numerous examples have occurred. We maintain that in view of this report no further inquiry is needed and every moment's delay in the Legislature's bringing reform to bear on this serious question may be responsible for further disaster. We believe that the compulsory use of fritted glaze would be a difficulty to small manufacturers, but if a system could be established by which these could be supplied with the glaze ready for use no valid objection on the score of increased working expenses or practical disadvantages could possibly be urged.

LORD CROMER'S REPORT ON EGYPT FOR 1897.

LORD CROMER'S Annual Report on the Finances, Administration, and Condition of Egypt makes its appearance this year later than usual. Dated Cairo, Feb. 27th, it was not presented to Parliament until the beginning of the present month (May). "As each successive year of the British occupation of Egypt passes by," says his lordship in conclusion, "two facts acquire an ever-increasing degree of prominence. The first is that the present *régime*, which has now lasted for fifteen years, has conferred, and is still conferring, the utmost benefit on the Egyptians and on all who are concerned in the welfare of Egypt. The second is that, whatever be the defects of that *régime*—and it cannot be doubted that, whether the matter be regarded from the English or from the Egyptian point of view, it possesses certain defects—the circumstances are such as to render it impossible to substitute any preferable system of government in its place. A satisfactory solution is certainly not to be found in any premature movement in the direction of more effective Egyptian autonomy, or in internationalising the Egyptian Government, or, lastly, in any combination of either of these two systems."

It would be impossible to state the case more clearly or more truthfully. Egypt having been sick unto death is now out of danger, if not absolutely convalescent, but she requires good food and plenty of it to enable her to grow perfectly strong and healthy. The defects alluded to by Lord Cromer are all remediable, but before they can be made to disappear it is essential that the English officials should be permitted freely and without exotic hindrance "to apply the knowledge they have acquired elsewhere to the good of Egypt." During fifteen years they have had many difficulties to contend with in addition to those indigenous to the soil, and although each year the former have been gradually lessening they still exist to a heartbreaking extent. It is really most unfair to ask the champions of law and order to continue fighting *in perpetuum* with their right arms tied behind their backs. Egypt is in many ways the country of marvels, and not the least of these is the fact that in spite of international entanglement, in spite of the glorious but expensive operations in the Soudan, our Egyptian Minister has been able to lay before Lord Salisbury "a record of appreciable progress in every branch of the Administration."

Following his customary arrangement Lord Cromer begins by explaining the accounts of the preceding twelvemonth, and notwithstanding the "intricacies of the Egyptian financial system" he contrives to convey a remarkably clear idea of his subject in wonderfully few words.[1] During the year the sums accruing to the two international reserve funds (which on Dec. 31st, 1897, showed a united credit-balance of £E.6,600,000), together with the revenue surplus of £E 433,000, amounted altogether to £E.1,443,000; but this large sum, unfortunately, was not clear gain. About £E.467,000 was realised from the sale of Daira and Domains land, which of course means a corresponding reduction in available assets, while the million remaining was more or less absorbed in order to cover extra military expenditure. Apparently the Egyptian Government still owes Her Majesty's Government the sum of £E.571,000; but when finally summing up the situation Lord Cromer is nevertheless able to say, "In spite of the expenses of the Soudan expedition, the aggregate indebtedness of Egypt has, during the past year, been decreased by £E.229,000, or £235,000," which is certainly a very satisfactory consummation.

Under the head "Medical Administration" some interesting facts are noticed. "Over 20,000 patients were received in the Government hospitals during 1897, being about 1000 in excess of the number in 1896. ..... Thirty-five new dispensaries were opened, thus extending medical aid to districts remote from a hospital. Four of the oases of the Libyan Desert, including that of Siwa, have now been provided with medical officers and dispensaries. ..... Kasr-el-Aini Hospital at Cairo, which contains accommodation for 420 patients, is now, in the opinion of competent authorities, in no degree inferior to similar institutions in the most advanced countries in Europe. ..... Four new hospitals were built in the provinces. ..... A bacteriological institute has been constructed and placed under a skilled bacteriologist." The most encouraging item of all, however, is quoted by Lord Cromer from a report by Rogers Pasha: "It is satisfactory to note not only a general improvement in organisation, but a higher tone amongst the Egyptian sanitary officials in the provinces, and now that the reorganisation of the Medical School is being seriously considered, I look for further improvement in this respect." Without a good and honourable executive no administrator can effect reforms. This elevation in tone is one of the most convincing signs of progress that we have so far observed. In this connexion Lord Cromer adds: "I hope next year to be able to report that the reorganisation of the Medical School has been carried into effect. The matter recently formed the subject of special inquiry at the hands of a highly qualified authority, Dr. Cooper Perry, who came from England for this purpose." Considerable space is also devoted to the Cairo Lunatic Asylum and hasheesh smoking.

In conclusion, although it is true that no great advance has taken place in the general sanitation of Egypt, still the subject is fully recognised as a most important one, and as soon as funds are forthcoming we shall no doubt hear of town sewerage on a large scale as well as other important sanitary works. In the meantime "some slight progress is being made"; 376 mosques have been cleansed, 465 cemeteries have been dealt with, the Khalij has been closed, a supply of pure drinking water has been provided in certain provincial towns, slaughter-houses have been built, and everywhere, but especially in Cairo, surface cleanliness has been immensely improved.

[1] The following example will suffice to exhibit the intricacy Lord Cromer alludes to: Owing to international exigencies the expenditure during 1897 had to be returned as £E.429,000 in excess of the estimate, whereas in reality it was £E.35,000 on the right side! A discrepancy of £475,000 sterling, or nearly half a million.

A FOURTH REPORT TO THE REGISTERED PRACTITIONERS OF ENGLAND AND WALES.

LADIES AND GENTLEMEN,—In my first report to you on the work of the General Medical Council (to which you appointed me as one of your Direct Representatives) I communicated to you instances of serious unconstitutional action on the part of the President of the Council. It was generally hoped, both within and without the Council, that with the appointment of a new President a stricter observance of constitutional procedure would ensue and that the efficiency of the work of the Council would be notably promoted.

I regret to be obliged to report to you that immediately upon the recent appointment to the Presidential chair there has been committed by the President a deliberate attack on the rights of individual members of the Council and a new and very serious infringement of constitutional government.

The facts are as follows. After the November Session of last year I commenced a research among the valuable

archives of the Council to determine — first, the exact position of many legal questions concerning the practice by medical men of their profession; secondly, the methods according to which the legal work of the Council is conducted; and thirdly, the cost to the Council of such legal work.

For several months—i.e., up to April 7th last—I carried out my investigations, visited the office from time to time, and inspected such documents as were necessary for the elucidation of different points, the Registrar producing the same when requested.

In the course of my work I became aware of certain grave matters which I communicated without reserve to Sir William Turner, the then acting chairman. Upon April 7th—the President having been elected on April 5th—I suddenly received notice from the Registrar that he was instructed by the President to refuse me any access to any document or financial paper belonging to the Council unless I had previously obtained the permission of the Executive Committee or of the Council. Having ascertained that the Registrar was acting solely under the President's instruction I wrote to the President and asked him: (1) by what regulation of the Council or legal enactment he sought to debar me of my right and privilege to inspect the documents of the Council for the purpose of preparing work for the Council's session; (2) whether he included all documents in his embargo; and (3) whether he considered that he, like his colleagues, was similarly debarred from inspecting any document unless he had previously obtained the permission of the Executive Committee or Council.

I regret to have to report that the President has complicated his extraordinary action by refusing to answer any of my questions.

The constitutional point thus raised is so simple that I need not extend the position save to explain that of course the Medical Acts and Standing Orders of the Council confer no such power, as that which the President claims, upon that officer, and that I am taking all steps that may be necessary to clear away this novel and foolish hindrance to my work for the execution of which you appointed me.

Cavendish-square, W., May 6th, 1898. VICTOR HORSLEY.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT, 1897.

THE Workmen's Compensation Act of 1897 is one of considerable moment to the medical profession. Out of the vast total of serious accidents to workmen, after making due allowance for those in which the question of compensation may be dealt with by agreement, there must remain many in which dispute will arise on that score, and among these not a few in which there will be need for judicial and authoritative decision of medical points upon which the evidence is inadequate. The Act provides for the appointment of medical referees for the purpose, and the Home Secretary with the concurrence of the Treasury has now formulated the conditions of appointment and the details of the machinery by which the references are to be made. They will be received with satisfaction by the profession. We are glad to see, by the memorandum issued recently,[1] that Sir Matthew White Ridley has recognised the importance of securing the services of men of experience and professional status for this new and important office which will often involve the delicate and difficult task of deciding where medical evidence is conflicting. The medical referee is not to be a witness, but rather an assessor or *amicus curiæ*, a judicial capacity in which a man of less experience than the medical witnesses would find himself in a false position. Wisely therefore the fees have been fixed upon a scale which, though not excessive, is liberal, and the formalities of reference seem to have been carefully planned to meet as far as possible the convenience of the referee and to spare him unnecessary trouble. The references will come to him through the registrar of the county-court, so that they will be in proper order from the outset. Without some provision of the kind there must have been many misdirected applications to the wrong referee, causing loss of time and needless trouble to all concerned. For this and other practical reasons the adoption of the county-court areas seems to offer distinct advantages, and the county-court circuits are conveniently wide and well-defined. It is implied in the memorandum that most of the appointments will be given to those having special experience on the surgical side of practice, and properly so, since the questions referred, whether of diagnosis or prognosis, will usually be of a surgical character. At the same time it seems to be contemplated that a certain number of physicians, and in some districts ophthalmic surgeons also, are to be selected, as the local circumstances may require.

It is difficult to form any estimate of the amount of work which will fall to medical referees in general and still more difficult in respect of any particular circuit. Time alone can show how many disputes will arise and how many of these will call for reference. There would seem to be little probability of extensive recourse to the kind of appeal allowed by Schedule I. (11)—appeal, that is, by the workman direct to the referee for a certificate of continued disability in case the employer proposes to terminate an allowance granted under the Act. Here the workman has to pay a fee to be agreed upon between the referee and himself and in this case alone the Government, having no power to repay the fee out of public funds, have not been able to fix its amount. It may be anticipated that the most reasonable fee will seem excessive and therefore be deterrent to the workman as the weekly allowance at stake must be small. Probably some sort of general understanding as to the fee to be asked in such cases will be arrived at and half-a-guinea would seem to be a proper sum. However, the amount of work under this head is not likely to be large.

The task of selection of suitable referees for every part of the United Kingdom is a sufficiently formidable one, especially as the time is short. That it will be made carefully and with due regard to the importance of the issues at stake is certain, and there should be no lack of candidates of the right stamp in any of the districts. The appointment of medical referee will come to be regarded as one of the most honourable public offices to be held by the profession, and it is a matter of no small importance that at the outset it should be undertaken by men of high standing.

[1] Vide THE LANCET, April 23rd, 1898.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE twenty-first meeting of the Royal Commissioners was held at the Council Chamber of the Westminster Town Hall on Monday, May 10th. With the exception of Sir John Dorrington and Mr. Cripps all the Commissioners were present. The commencement of the sitting was occupied with the examination of Mr. Deacon, who, on the suggestion of Sir George Barclay Bruce, had prepared a paper giving in tabular form a digest of the evidence which he had prepared to give the Commissioners at the last meeting. This table we hope to print *in extenso* shortly. Sir Alexander Binnie, the chief engineer of the London County Council, was present at the sitting and was prepared to give evidence with regard to the diagrams which Mr. Deacon had put in at a former meeting of the Commissioners. Arrangements had, however, been made that the representatives of the several London vestries should be heard at this sitting and Sir Alexander Binnie's evidence was therefore postponed until next week. The evidence given by Mr. Deacon with regard to the reservoirs and the comparative cost of the Welsh scheme and the Staines reservoir scheme will be best understood from the study of the table which we shall publish shortly, and in the present place we record the chief facts which were given in the course of his cross-examination.

Mr. DEACON said that the length of the aqueduct from Wales to London would be about 150 miles. With regard to the distribution of the water Mr. Deacon thought that the water from Wales and from the Thames should be distributed mixed or separate as occasion required. He did not approve of a supply of water from the Thames and looked upon it as a necessary evil, for an evil it undoubtedly was. The water derived from Wales would probably be filtered before distribution and the filtration would take place at Elstree, where the chief reservoir north of the Thames would

be situated. There was no sanitary reason for the filtration of the water.

In answer to Sir GEORGE BARCLAY BRUCE the witness said that there was very little peat in the Welsh water, and in answer to Mr. MELLOR he stated that it contained only a small quantity of sand after a heavy rainfall, that this sand would be deposited in the reservoir in Wales, and that none of it would pass through the aqueduct. The height of the Welsh reservoir was to be 606 ft., and that of the reservoir at Elstree 312½ ft., above the sea level.

In answer to Mr. RICKARDS, counsel for the Chelsea Company, the witness said that the level of the filter beds at Elstree would be about 30 ft. below that of the reservoir, and water to Westminster which is at present supplied by the Chelsea Company would be supplied from Elstree. In another answer to Mr. Rickards the witness said that he did not remember the height of the Putney Heath reservoir, which is the one which at present supplies Westminster with water. With regard to the calculations he had given in his table he had not reckoned the cost of connecting the reservoir at Elstree with the reservoirs which were at present in the hands of the various metropolitan water companies. With regard to the amount of the flow of the Thames the witness pointed out that if a largely increased supply were taken from the Thames so that the flow of the river was reduced to 200,000,000 gallons a day, the amount of water passing down the Thames through London would be reduced to a greater extent than had previously been the case. It followed from that that in a year of drought during the summer and autumn months the state of the River Thames would be more impure than it is at present in consequence of the further reduction of the flow. With regard to the expenses which would be incurred in carrying out the Welsh scheme in addition to those given in the table, the witness said that he had not allowed anything for Parliamentary and legal expenses, and an allowance for these must be added to that necessary to carry out the connexions between the new reservoirs which would be made to receive the Welsh water and those already in use and belonging to the metropolitan water companies.

In answer to Sir GEORGE BARCLAY BRUCE the witness stated that the filtration of the water at present was not adequately carried out. Dr. Frankland and Dr. Koch agreed that drinking water should not contain more than 100 bacteria per cubic centimetre. At the present time water supplied by the metropolitan companies sometimes contained a great excess of bacteria; in one case as many as 16,000 instead of 100 had been found per cubic centimetre. Filters were not always in proper working order. Dr. Frankland's reports gave an example in which a filter bed belonging to the Southwark and Vauxhall Water Company had been used with unsatisfactory results, and he had also recorded a "microbial epidemic" which had affected all the London water except that supplied by the New River Company.

In answer to Major-General SCOTT the witness said that it was true that the conditions obtaining in the rockwork below the filter-beds had not been thoroughly investigated, but the witness thought that the microbes passed through the filter-beds.

In answer to the CHAIRMAN he said that the chief causes of difficulty with regard to the filtration were (1) deficiency in the area of filter beds; (2) deficient storage capacity which prevented the water from "settling" for a sufficient time before it was put on the filter beds; and (3) improper management of the filter beds. Improvements had recently taken place, but formerly it was not unusual for a workman to go round and make holes in a filter bed to allow water to pass through.

Mr. WILLIAM FRANCIS DEWEY, vestry clerk to the parish of St. Mary, Islington, gave evidence with regard to the water-supply of that district. The parish of Islington, he said, contained over 3000 acres. The population in 1895 was over 336,000 and at the present time it was computed to be 350,000. The annual rateable value amounted to nearly £2,000,000. The vestry had undertaken to supply electricity to the parish for public and private purposes and had taken over the powers of the Commissioners for Baths and Public Washhouses. The water-supply was derived from the New River Company and the supply had been found on the whole to be satisfactory "both as to quantity and quality," the vestry, however, complained of the price which they had to pay for water which was used for non-domestic purposes—for flushing sewers, for baths, and for the works connected with electric lighting. The amount of water used for baths was very considerable. At the Hornsey-road baths nearly 38,000,000 gallons were used annually and at Tibberton-square baths, 24,000,000 gallons. The price charged for this water was at the rate of 7½*d.* per 1000 gallons. For street watering nearly 64,000 gallons were used, for which the price paid was 8½*d.* per 1000 gallons. The charges made by the company were based on the New River Company Act of 1852 (15 and 16 Vict. cap. cxl.).

On referring to the Act, the CHAIRMAN suggested that if the water were taken by meter the statutory charge was 6*d.* per 1000 gallons, and that if the vestry bought the water by meter that that was the price which should be paid for it. The witness said that the vestry had protested against the price which they were asked to pay for the water and he was given to understand that the New River Company would rather not have their custom. The only grievance which the vestry had against the company was the excessive price which they had to pay. At the present time an artesian well was being sunk for the vestry and the engineer reported that there was a good supply.

Mr. BAGGALLAY, Q.C., on behalf of the New River Company, asked how it was that the vestry, if they were aggrieved as to the price which they paid, did not avail themselves of the Act of 1847 (10 Vict. cap. xvii.). Under this Act the price might have been fixed by two justices. The following may be quoted as the reasoned opinion of the vestry as to the charges at present made:—

> The vestry approves of the provisions of the Metropolitan Water Act of last year so far as those provisions extend, but is of opinion that its scope should be extended so as to provide for the constitution of a tribunal for apportioning an equitable rate of charge for non-domestic supplies and that such tribunal should also be empowered to settle disputes as to the rates of charge for such supplies similar to that provided for by Section 68 of 10 and 11 Vict. cap. 17, for determining disputes as to the annual value of a tenement supplied with water.

The CHAIRMAN suggested that this inquiry might possibly awaken the vestry to a knowledge of the present right which they had to insist on the paying of nothing in excess of the statutory charges.

Mr. HUGH ALEXANDER, chief sanitary inspector for the parish of St. Leonard, Shoreditch, gave evidence on behalf of his vestry. Resolutions to the following effect have been passed by the vestry:—

> 1. That this vestry are of opinion that the management of the water-supply of the metropolis should be under one authority, and that authority should be the London County Council. 2. That unless and until the water-supply is placed under the management of the London County Council this vestry are of opinion (*a*) that the local authorities should have the power to approve or disapprove, from a sanitary standpoint, of the cisterns or other means of storage enforced by the water companies, and to require a sufficient pressure to supply the highest dwellings in their respective districts; (*b*) that local authorities should be empowered to expend money for the purpose of having the water analysed from time to time. 3. That this vestry are of opinion that the area of supply of the East London Waterworks Company in this parish should be transferred to the New River Company (in accordance with the vestry's resolution of Sept. 15th, 1896).

Mr. ALEXANDER said that the East London Water Company had introduced a constant supply within the parish for more than twenty years. A constant service was introduced by the New River Company to the district in the year 1877 and cisterns were removed from the houses. In the summer of 1895 the East London Water Company ceased to give a constant supply. A Commission of Inquiry was appointed by the Government and Colonel Ducat and the late Dr. Barry reported that in their opinion the inconvenience experienced by consumers was much aggravated by the want of proper means for domestic storage of water; and, further, that for the protection of the consumer against unavoidable temporary intermissions of the supply they considered that there would be distinct advantage in having properly designed means for storage of water in houses; and that although nothing could be further from their intention than to advocate any return to the old defective cisterns with their moveable wooden covers they advocated the provision of "properly designed cisterns." In consequence of this report cisterns had been reintroduced, but they were not satisfactory and the vestry had no power to insist on the form of cistern which should be adopted. Mr. Alexander showed a drawing of a patent cistern and air valve which he had invented. The cistern contained 200 gallons. He wished, he said, that it had been invented by someone else so that he might have spoken more fully of its merits. He pointed out, however, that the cistern was self-cleansing, the principle being, as the Chairman remarked, that nothing accumulated at the bottom of the cistern because in consequence of its sloping arrangement all solid

particles at once went down the supply pipe to the consumer. In the course of his evidence the witness showed samples of water which he stated had been taken from the cisterns of the inhabitants of Shoreditch. One of these bottles contained a deposit of nearly an inch of solid matter and another contained a dead mouse. At the present time the witness said that both the New River and the East London companies insisted that cisterns should be supplied to houses to which they gave fresh supplies. He contended that it was impossible for vestries to ensure that cisterns should be kept carefully cleansed and that it was necessary that properly designed cisterns should be provided. The only one with which he was acquainted was that which he had himself invented. The number of supplies in the district was 15 800 and the cost of the cistern which he had invented was £10.

Towards the end of the sitting Mr. HENRY GEORGE HILLS gave evidence on behalf of the board of works of the Wandsworth district.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN extraordinary meeting of the Council was held on May 4th, Sir WILLIAM MACCORMAC, Bart., the President being in the chair.

Mr. C. S. Tomes, F.R.S., was introduced and after signing the by-laws was admitted a Fellow of the College.

A letter was read from the Secretary of State for Foreign Affairs enclosing a copy of a despatch from the British Ambassador at Rome, which reported that the Italian Government do not contemplate making any change in the laws with respect to the status of medical men of other countries in Italy.

The PRESIDENT stated that he had written to Lord Salisbury expressing the thanks of the Council for the steps he had taken in the matter.

The Council proceeded to consider the report of the General Medical Council on the Midwives Registration Bill and finally adopted in the main the conclusions at which the General Medical Council arrived, embodying their opinion in the following resolutions:—

(1) That the Council consider that it is desirable that measures should be taken to protect lying-in women of the poorer classes from the grave risk which they now incur from the unregulated practice of midwives, many of whom are ignorant and unskilful, and most of whom pursue their calling without due medical supervision.

(2) That to this end it is desirable that every woman who, not being a registered medical practitioner, engages for gain in practice as a midwife should be subjected to legal regulation and control.

(3) That any measure which proposes merely to protect the title of "Midwife," however defined, and does not make illegal and penal the unlicensed practice of midwifery for gain, cannot be regarded as offering a sufficient safeguard in the interest of the public health.

(4) That some central body should be established by Parliament whose functions should include the framing of the conditions under which midwives may be licensed and of the regulations under which alone they shall be allowed to practise.

(5) That the conditions and regulations so framed should be subject to the approval of the General Medical Council, and if and when so approved should be issued to the local sanitary authorities by the State Department which is concerned with the public health.

(6) That every woman before beginning to practise as a midwife in any district should be required to take out a licence to be granted by the local sanitary authority of the district under the prescribed conditions and regulations. That such licence should be subject to annual renewal and should be revocable at any time in case the holder is proved to have infringed any of the prescribed regulations.

(7) That any unlicensed woman, whether calling herself a midwife or not, who, not being registered under the Medical Acts, practises as a midwife for gain in any district should be made liable to a substantial penalty.

(8) That the conditions under which licences are granted should include the production of satisfactory evidence of character and of training and experience in the conduct of natural labour and in the nursing of lying-in women and new-born infants.

(9) That the regulations under which licensed midwives are required to practise should include provisions securing that the midwife shall immediately seek qualified medical assistance in every case which presents symptoms of difficulty, abnormality, danger, or disease on the part of the mother or of the new-born infant.

And that in so far as the Bill is not in accordance with these general principles the Council do not regard it as offering an adequate solution of the question under consideration and would earnestly deprecate its passing into law in its present form.

It was further resolved that these resolutions should be communicated to the Privy Council and also to those who have charge of the Bill in the House of Commons.

The Council also directed that Mr. Rowland Humphreys, the honorary secretary of the Midwives Bill Committee, should be informed of the decision of the Council.

A letter was read from the Solicitor of the College reporting that the claim of the College for exemption from corporation duty was heard on April 28th and 29th and that judgment was given in favour of the Crown except as regards the conservator's house, which was considered to be exempt from duty, this partial success relieving the College from having to pay the costs of the Crown.

The question of the desirability of appealing against the decision of the Court was postponed to the next meeting.

THE ROYAL SOCIETY CONVERSAZIONE.

THE past year of scientific work has been a busy one judging from the harvest of results exhibited in the rooms of the Royal Society at Burlington House last Wednesday. In number, interest, and variety the exhibits were, we venture to think, a distinct advance on recent years. Every branch of science seems to have contributed its own piece of evidence of the activity of the workers concerned. And the audience was an appreciative one, finding subject for reflection and fruitful discussion on every side.

Perhaps the latest advance in medicine was best represented in the instructive exhibition for which Sir Richard Thorne, K.C.B., F.R.S., and Dr. Copeman were jointly responsible. The subject of the exhibit was the bacteriology of vaccine calf lymph in which the unquestionable advantages of glycerinated lymph were convincingly illustrated. The exhibit was divided into two sections, glycerinated and unglycerinated lymph, with cultures showing the growth of adventitious microbes in the one, and the absence of development in the other. Medical visitors would be attracted, too, by the simple forms of sphygmo-manometers shown by Dr. Leonard Hill and Mr. Harold Barnard, F.R.C.S. The instruments possess the advantage that in measuring arterial pressure the charges due to temperature for barometric pressure are avoided. Photography is an ever-widening field of study and begins now to form a large portion of the annual exhibits. Mr. Mackenzie Davidson showed his ingenious and accurate localising apparatus and close by could be seen some excellent and realistic stereoscopic x-ray photographs by means of a Wheatstone stereoscope. Mr. Campbell Swinton exhibited some pretty x-ray effects. He demonstrated the existence of a positively electrified stream proceeding from the anode and in the opposite direction to the cathode stream. On the same table was a Roentgen camera showing the position, dimensions, and form of the source of the x rays in a Crookes tube. The image of the active anti-cathode area is thrown upon a fluorescent screen by means of a pinhole, and the image may be photographed. Mr. Swinton also showed a cathode ray lamp consisting of an x-ray tube containing a piece of lime. The electrical bombardment of molecules upon this substance raises it to a very high temperature and it at length becomes brilliantly incandescent and as powerful as the arc light. It is said that the efficiency of the light appears to be much superior to that obtained in ordinary incandescent electric lamps and may even exceed that of the arc. The application of the Wimshurst machine to radiography was shown by Mr. Wimshurst himself. The advances in colour photography were illustrated in Dr. Selle's process by Mr. R. B. Roxby. In this process the negatives are taken through red, blue and green glass screens respectively. From these, three collodion positives are produced, which after development in complementary colour baths are super-imposed, the result giving the complete picture. Mr. C. V. Boys showed some little glass plates made with 230 zones inscribed thereon, in consequence of which they become similar to a lens in effecting the formation of an image. Photographs taken with these lens substitutes were exhibited. The extraordinary photographic results recently obtained by Dr. W. J. Russell formed an exceedingly interesting exhibit. The pictures taken on photographic plates were produced as is now assumed by vapours from certain metals and certain organic bodies. These emit a radiation which acts upon the silver film. One very interesting application of the discovery is the intensification of faded writing by its means. Thus on wrapping a nearly illegible

piece of writing by Priestly in contact with a negative a photographic result was obtained decidedly more distinct than the original. The process is, of course, conducted in the dark.

Wireless telegraphy was practically demonstrated by Professor Oliver Lodge and Dr. Alexander Muirhead. One station was at the end of the library and the other in the secretary's room, each station receiving and transmitting alternately. The increasing application of micrography in the arts and industries was in evidence. Thus Mr. T. Andrews showed by means of micrographic illustrations the deterioration in steel rails under known conditions of main line service. This study has afforded a means of determining the microscopic structure and composition best adapted to ensure endurance and safety in rail service. A similar demonstration was given by Professor Roberts-Austen and Mr. J. E. Stead, the former also exhibiting an ingenious apparatus designed by M. Berthelot for the determination of high temperatures. Close by, Mr. A. E. Tutton showed an ingenious method particularly applicable to the investigation of the thermal expansion of crystals. An exhibit which attracted considerable interest was that of Professor W. A. Herdman and Professor R. Boyce showing the causes of the colouration of healthy and unhealthy green oysters and the connexion between oysters and disease. The presence of a copper compound was micro-chemically demonstrated. The Marine Biological Association had its usually occupied corner and this time the subject of exhibition was "The Adaptations of Marine Animals to their Environmet, illustrated by Living Examples of the Higher Crustacea." One of the largest displays was the excellent series of photographic pictures brought back by Sir Norman Lockyer from the expedition which took observations in India of the total solar eclipse of Jan. 22nd, 1898. Similar observations made by the Eclipse Committee of the British Astronomical Association were also admirably illustrated in a group of photographs. A pretty experiment, which was missed by many because it was demonstrated in a room on the ground floor, was that undertaken by Mr. C. T. R Wilson. It referred to the production of cloud by the action of ultra violet light. When the light from an arc lamp is brought by means of a quartz lens to a focus within a vessel containing moist, dust-free air, a bluish fog gradually develops along the path of the light. The effect is entirely prevented if the ultra violet rays be cut off by interposing a sheet of glass or mica, no cloud or rain resulting under these conditions even when supersaturation is brought about by sudden expansion. Possibly the small particles which give rise to the blue of the sky are produced by the ultra-violet rays of sunlight absorbed in the upper layers of our atmosphere. On the same floor was exhibited the apparatus used in the navy for determining the position of ships afar off. The accuracy of this range-finder under good conditions of working may be taken as 1 per cent. at 3000 yards. The instruments were exhibited by Professor Barr and Professor Stroud. Lastly, Mr. Joseph Gould repeated some of his instructive experiments in relation to resonance, and the latest addition consisted of a demonstration of dust-heaps vibrating under the influence of a vibrating bar of metal, and bursting in a most odd way into whirling nebulæ and ultimately condensing into gravitating systems of circular mounds.

The guests and Fellows were received by the President, Lord Lister, and there was a distinguished and very representative company present.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6351 births and 3750 deaths were registered during the week ending May 7th. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 21·5 to 18·4 per 1000, further fell last week to 17·4. In London the rate was 16·9 per 1000, while it averaged 17 8 in the thirty-two provincial towns. The lowest rates in these towns were 10·9 in Croydon, 12·4 in West Ham, 12·9 in Cardiff, and 13 3 in Burnley; the highest rates were 20·8 in Newcastle-upon-Tyne, 20·9 in Huddersfield, 21·1 in Oldham, and 26·2 in Liverpool. The 3750 deaths included 408 which were referred to the principal zymotic diseases, against 473 and 468 in the two preceding weeks; of these, 157 resulted from measles, 114 from whooping-cough, 50 from diphtheria, 34 from diarrhœa, 29 from scarlet fever, 23 from "fever" (principally enteric), and 1 from small-pox. No death from any of these diseases was recorded last week in Birkenhead, Burnley, Preston, or Huddersfield; in the other towns they caused the lowest death-rates in Portsmouth, Croydon, and Swansea; and the highest rates in Wolverhampton, Derby, Gateshead, Sheffield, and Liverpool. The greatest mortality from measles occurred in London, Bristol, Wolverhampton, Halifax, and Bradford; from scarlet fever in Burnley; and from whooping-cough in Liverpool, Salford, Sheffield, Gateshead, and Newcastle-upon-Tyne. The mortality from "fever" showed no marked excess in any of the large towns. The 50 deaths from diphtheria included 27 in London, 3 in West Ham, and 3 in Liverpool. One fatal case of small pox was registered in Gateshead, but none in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in those hospitals and in the London Fever Hospital was 2271 on Saturday last, May 7th, against 2384, 2334, and 2302 at the end of the three preceding weeks; 209 new cases were admitted during the week, against 217, 241, and 205 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 283 and 274 in the two preceding weeks, further declined last week to 226 and were 104 below the corrected average. The causes of 51, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Cardiff, Manchester, Leeds, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Salford, Bradford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 24·2 to 21·8 per 1000 in the five preceding weeks, further fell to 21·7 during the week ending May 7th, but exceeded by 4·3 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·7 in Leith and 18 6 in Paisley, to 23·1 in Dundee and 34 0 in Perth. The 654 deaths in these towns included 29 which were referred to whooping-cough, 27 to measles, 24 to diarrhœa, 5 to "fever," 4 to scarlet fever, and 1 to diphtheria. In all, 90 deaths resulted from these principal zymotic diseases, against 88 and 96 in the two preceding weeks. These 90 deaths were equal to an annual rate of 3 0 per 1000, which was 1·1 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 25 and 34 in the two preceding weeks, declined to 29 last week, and included 18 in Glasgow, 4 in Paisley, 2 in Edinburgh, and 2 in Aberdeen. The deaths from measles, which had increased from 14 to 35 in the three preceding weeks, declined to 27 last week, of which 23 occurred in Glasgow and 2 in Edinburgh. The deaths referred to different forms of "fever," which had been 5 and 2 in the two preceding weeks, rose again to 5 last week, and included 4 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 151 and 137 in the two preceding weeks, further declined to 129 last week, and were slightly below the number in the corresponding period of last year. The causes of 29, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·3 and 25·4 per 1000 in the two preceding weeks, declined again to 24·5 during the week ending May 7th. During the past four weeks the death-rate in the city has averaged 25·1 per 1000, the rate during the same period being 17·8 in London and 20·1 in Edinburgh. The 164 deaths registered in Dublin during the week under notice showed a decline of 6 upon the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 13 and 9 in the two preceding weeks; of these, 3 resulted from whooping-cough, 3 from

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1898.

* Including 28 cases of membranous croup.

† Including deaths from membranous croup.

"fever," 1 from scarlet fever, 1 from diphtheria, and 1 from diarrhœa. These 9 deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 2·4 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had been 2 and 3 in the two preceding weeks, were again 3 last week. The deaths referred to different forms of "fever," which had been 2 in each of the two preceding weeks, rose again to 3 last week. The mortality from scarlet fever and from diarrhœa corresponded with that recorded in the preceding week. The 184 deaths in Dublin last week included 36 of infants under one year of age, and 40 of persons aged upwards of sixty years; the deaths of infants showed a further increase, while those of elderly persons were below the numbers recorded in any recent week. Five inquest cases and 1 death from violence were registered; and 68, or more than a third, of the deaths occurred in public institutions. The causes of 13, or nearly 8 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1898.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during April in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 7·1 per 1000 of the population, estimated at 4,504,766 persons in the middle of this year. In the three preceding months the rates had been 8·2, 7·8, and 7·4 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Paddington, St. James Westminster, Hampstead, St. Giles, St. Martin-in-the-Fields, City of London, and Whitechapel; while they showed the largest excess in Fulham, Hackney, Strand, Shoreditch, St. Olave Southwark, Battersea, and Lee. Four cases of small-pox were notified in London during April, against 3 in each of the three preceding months; of these, 1 belonged to Westminster, 1 to Marylebone, and 1 to Camberwell sanitary areas. No small-pox patients were under treatment during last month in any of the Metropolitan Asylum Hospitals. The prevalence of scarlet fever in London showed a slight increase upon that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Poplar, St. George Southwark, Battersea, Lee, and Plumstead. The Metropolitan Asylum Hospitals contained 2770 scarlet fever patients at the end of April, against 2621, 2640, and 2358 at the end of the three preceding months; the weekly admissions averaged 218, against 232, 214, and 208 in the three preceding months. The prevalence of diphtheria in London during April showed a further decline from that recorded in the two preceding months; this disease was proportionately most prevalent in Chelsea, Westminster, Hackney, Strand, Holborn, St. George-in-the-East, and Lee sanitary areas. There were 923 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of April, against 1055, 1042, and 1009 at the end of the three preceding months; the weekly admissions averaged 111, against 132, 140, and 129 in the three preceding months. The prevalence of enteric fever in London during April showed a slight decline from that recorded in March; among the various sanitary areas this disease showed the highest proportional prevalence in St. Martin-in-the-Fields, Bethnal Green, St. Saviour Southwark, and Greenwich. The Metropolitan Asylum Hospitals contained 59 enteric fever patients at the end of April, against 106, 84, and 64 at the end of the three preceding months; the weekly admissions averaged 12, against 11 and 12 in the two preceding months. Erysipelas was proportionally most prevalent in Shoreditch, Bethnal Green, St Olave Southwark, and Bermondsey sanitary areas. The 23 cases of puerperal fever notified in London during April included 4 in St. Pancras, 3 in Stoke Newington, 2 in Battersea, and 2 in Plumstead sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, April 30th, the deaths of 6240 persons belonging to London were registered, equal to an annual rate of 18·1 per 1000, against 22·0, 21·4, and 20·8 in the three preceding months. The lowest death-rates in the various sanitary areas were 11·5 in St. Martin-in-the-Fields, 13·1 in Lee, 13·2 in Hampstead, 14·3 in City of London, and 14·5 in Fulham and in Wandsworth; the highest rates were 22·1 in Bethnal Green, 22·8 in Marylebone, 23·0 in Strand and in St. George-in-the-East, 23·1 in Clerkenwell, and 30·8 in Holborn and in St. Luke. During the four weeks of April 966 deaths were referred to the principal zymotic diseases in London; of these, 461 resulted from measles, 246 from whooping-cough, 132 from diphtheria, 54 from scarlet fever, 45 from diarrhœa, 27 from enteric fever, and 1 from an ill-defined form of continued fever. These 966 deaths were equal to an annual rate of 2·8 per 1000; no fatal cases of any of these diseases were registered during the month under notice in St. Martin-in-the-Fields or in the City of London; in the other sanitary areas they caused the lowest death-rates in Hampstead, St. Pancras, Whitechapel, St. Saviour Southwark, St. George Southwark, Newington, and Bermondsey; and the highest rates in Westminster, Islington, Holborn, Clerkenwell, St. Luke, Bethnal Green, and Poplar. The 461 fatal cases of measles were 184 above the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Paddington, Hammersmith, Westminster, Marylebone, Islington, Holborn, Bethnal Green, and Rotherhithe sanitary areas. The 54 deaths referred to scarlet fever were 11 below the corrected average number; the mortality from this disease was highest in Shoreditch, St. George Southwark, Bermondsey, and Lewisham sanitary areas. The 132 fatal cases of diphtheria were within 3 of the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Chelsea, Westminster, Hackney, Clerkenwell, Bethnal Green, and Lee. The 246 deaths from whooping-cough were 39 below the corrected average number; the mortality from this disease was highest in Westminster, St. Luke, Shoreditch, Bethnal Green, St. George-in-the-East, and Poplar sanitary areas. The 27 fatal cases of enteric fever were 3 below the corrected average; the mortality from this disease showed no marked excess last month in any of the sanitary areas. The 45 deaths from diarrhœa were 9 below the corrected average number. In conclusion, it may be stated that the mortality in London last month from these principal zymotic diseases was nearly 14 per cent. above the average, owing to the excessive fatality of measles, the deaths from each of the other zymotic diseases being below the average.

Infant mortality in London, measured by the proportion of deaths of children under one year of age to registered births, was last month equal to 137 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Fulham, Stoke Newington, Strand, City of London, Whitechapel, and Lee; and the highest rates in St. James Westminster, Hampstead, Holborn, St. Martin-in-the-Fields, St. Luke, St. Olave Southwark, and Woolwich.

THE SERVICES.

NAVAL MEDICAL SERVICE.

THE under-mentioned Fleet-Surgeons have been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets: Thomas Lyle Horner; Edward Elphinstone Mahon, C.B.; and John C. Birkmyre Maclean.

The following appointments are announced:—Deputy Inspectors-General: Thomas Bolster to Hong-Kong Hospital; Thomas L. Horner to Haslar Hospital; and William Cook to the *Crescent*. Fleet-Surgeons: Richard D. White to the *Ramillies;* John Tyndall to the *Excellent;* Gerard J. Irvine to Haslar Hospital; and William B. Drew to Royal Marine Depôt, Walmer. Staff-Surgeons: Norman L. Richards to the *Dido* and William S. Lightfoot to the *Pembroke*. Surgeons: A. E. Kelsey to the *Victory*, additional; D. W. Hewitt to the *Vivid*, additional; and Algernon C. Bean to the *Triton*.

ARMY MEDICAL STAFF.

Surgeon-Major H. E. R. James succeeds Surgeon-Lieutenant-Colonel H. Grier as second in command and Instructor of the Army Medical Depôt and Training School, Aldershot. Surgeon-Captain Jameson and Surgeon-Captain Beach join at Woolwich for duty. Surgeon-Major Carl[illegible]

is transferred from Dublin to the Cork District. Brigade-Surgeon-Lieutenant-Colonel Supple has embarked in the *Dunera* for service in South Africa.

Surgeon-Major Patrick J. Nealon, M.D. R.U.I., half-pay, retires from the Service, receiving a gratuity. Surgeon-Major Francis H. Treherne, from the Seconded List, to be Surgeon-Major, vice E. D. Bringhurst-Farmar.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Colonel Hendley, C.I.E., is appointed to be Inspector-General of Civil Hospitals, Bengal. The services of Surgeon-Major Thompson (Madras), and Surgeon-Major Kavasji Cursetji Sanjana (Madras) are replaced at the disposal of the Government of Madras. Surgeon-Lieutenant-Colonel Ranking, Secretary to the Board of Examiners, is appointed to act temporarily as Surgeon-Superintendent of the Presidency General Hospital, Calcutta, in addition to his own duties, vice Brigade-Surgeon-Lieutenant-Colonel Crombie, retired.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major G G. Sparrow resigns his commission.

VOLUNTEER CORPS.

Artillery: 1st Argyll and Bute: Thomas Harvey Thomson, M.D., to be Surgeon-Lieutenant. *Rifle:* 1st (Hallamshire) Volunteer Battalion the York and Lancaster Regiment: Surgeon-Captain J. W. Martin to be Surgeon-Major. 2nd (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Major M. H. Taylor to be Surgeon-Lieutenant-Colonel.

THE ROYAL MILITARY TOURNAMENT.

The air is so full of "wars and rumours of wars" that little or nothing is necessary at the present moment to stimulate public enthusiasm in regard to things naval and military. Nevertheless we welcome the announcement that the Royal Military Tournament will for the nineteenth time be held at the Agricultural Hall on Thursday, May 19th, and be continued until June 2nd. The pageant "Shoulder to Shoulder" will be representative of the periods 1596, 1704, 1801, and 1884, when the sister services fought side by side at Cadiz, at Gibraltar, at Alexandria, and at El Teb. The "combined display," or mimic battle, at the conclusion of each performance will this year be descriptive of the capture of Benin city and among the sailors and marines taking part in the display are many who actually shared in the dangers and honours of the expedition. During the earlier portion of the tournament the military ride will be carried out by the Royal Horse Guards (the Blues), while during the latter part of the time it will be performed by the Seventh (Princess Royal's) Dragoon Guards from Norwich. The Royal Navy will be present in twice the strength of last year and not only will they take part in the pageant and combined display but they will also give performances as a field battery, armed both with 9-pounder and 12 pounder guns. That Major-General Henry Trotter and his committee will be well supported we have no doubt, but we may remind our readers that the entire profits of the tournament, with the exception of an amount sufficient for necessary expenses, are distributed among naval and military charities.

THE SOUDAN EXPEDITION.

The active Soudan policy lately inaugurated has necessarily given rise to certain corresponding disadvantages. Although the amount of money so far spent has been almost infinitesimal in comparison with the magnificent results achieved "it is, nevertheless, obviously true," in Lord Cromer's estimation, "that that money might have been spent on other objects of unquestionable utility." It is impossible to eat one's cake and have it. The Egyptian Legislative Council and Assembly approve of the Soudan expedition and in the same breath press on the Egyptian Government the desirability of reducing taxation. Sir Elwin Palmer is an able financier, but we venture to think that even his powers will be unequal to the problem of taking one from one and leaving one. The total Soudan expenditure since March, 1896 (when it was decided to advance on Dongola), inclusive of a sum of £E.213,000 which is provided for in the estimates for the current year, has been £E.1,850,000, or in round numbers £1,900,000 sterling. Of this amount about £E.750,000 has been expended on railways and telegraphs. The balance represents extraordinary military expenditure, properly so-called; and considering the magnitude of the operations—to say nothing of the complete success which has attended Sir Herbert Kitchener's arms—it is probable that never before were similar results obtained at such an inexpensive rate.

ANNUAL MESS OF THE VOLUNTEER MEDICAL STAFF.

Sir Joseph Fayrer, Bart., presided at a most successful mess of the Volunteer Medical Staff at Limmer's Hotel on May 4th. The date unfortunately clashed with the Lord Mayor's banquet to the medical profession, yet the number who sat down was only one less than last year. The toasts were "The Queen," "H.R.H. the Prince of Wales, President of the Volunteer Medical Association," "The Volunteer Medical Association," "The Visitors" and "The Chairman." Among the guests were Colonel Campbell and Colonel J. W. Smith-Neil, Scots Guards; Colonel Alt, Colonel Roberts, Colonel Hardcastle, Colonel Kellar, Colonel Leese, Colonel Lucas, and Surgeon-Major Bedford, A.M.S., &c. Major-General Trotter and Surgeon-Colonel O'Farrell, P.M.O., who had accepted invitations, were on the sick list and unable to attend. Surgeon-Captain C. Graham Grant was responsible for the excellent musical programme and Surgeon-Captain R. Fletcher for the general arrangements. Sir Joseph Fayrer, in response to the toast of his health, made an eloquent speech on the present condition and the hopes and aspirations of the Army and Volunteer Medical Services.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The official inspection and examination of the present class of regimental stretcher-bearers took place on Wednesday last at the Queen's Westminster headquarters, James-street, S.W., when a large number of officers, non-commissioned officers, and men, representatives of the volunteer corps of the Home District, went through a searching ordeal at the hands of Surgeon-Major E. M. Wilson, C.M.G., Army Medical Staff, and Surgeon-Lieutenant R. M. Cooper, Grenadier Guards. After the inspection in line the class was taken through the stretcher and hand-seat drill and then each member had a *viva voce* examination in "First aid." At the conclusion Surgeon-Major Wilson addressed the men and expressed himself very pleased with the excellent manner in which the work had been done throughout. He then presented the prizes to those who were successful at the prize competition held during the previous week. The London Scottish Rifle Volunteer Corps won the Hamilton Challenge Bowl and will hold the same until the next competition. In the unavoidable absence of Brigade-Surgeon-Lieutenant-Colonel P. B. Giles, Surgeon-Captain R. R. Sleeman was in command.

THE SPANISH-AMERICAN WAR.

There has been really nothing of great importance to chronicle since the reception of the news of the crushing defeat of the Spanish fleet at Manila. The expected naval battle in the vicinity of Puerto Rico has not taken place. The United States are sending 5000 troops as a landing force at Manila and it is asserted that, in spite of the transport and military difficulties and the prejudicial effects on the health of the troops which will probably have to be encountered at this season, an American force will soon be sent to Cuba. The United States will naturally spare no effort to bring the war to an end if possible. Surgeon-General Senn (who ranks as a lieutenant-colonel) of Illinois has relinquished a lucrative practice to join the medical service of the United States.

THE ARMY BOOT.

With reference to the proceedings which have recently taken place in the House of Commons regarding the army boot Mr. William Hickson, President of the Northampton Manufacturers' Association, writes to the *Times* calling attention to the fact that the army contracts have not been undertaken in the borough of Northampton for several years and stating that Northampton manufacturers could, if they had the opportunity, supply any number of boots more suitable than the article now delivered.

DEATHS IN THE SERVICES.

Surgeon-Captain James Walker, A.M.S., at Jacobabad, Upper Sindh, on April 23rd, from pneumonia, aged twenty-eight years.

Deputy Surgeon-General Samuel Bowen Partridge, I.M.S. (Bengal), C.I.E., at his residence at Anerley, aged sixty-nine years. The deceased was one of Her Majesty's Honorary Surgeons and was lately a member of the India Office Medical Board. He also at one time held the post of

Professor of Surgery and Anatomy at the Calcutta Medical College and was surgeon to several hospitals in India.

HER MAJESTY'S VISIT TO NETLEY.

The arrangements made for the Queen's visit to Netley to-day (Saturday) are:—Her Majesty will leave the Windsor station of the Great Western Railway at half-past two o'clock in the afternoon by special train and will travel *viâ* Reading to Basingstoke; thence the Royal journey is over the South-Western line to Netley, which will be reached at half-past four. The Queen will leave Netley on her return at half-past five and arrive at Windsor at half-past seven.

THE LATE INDIAN BORDER WAR.

The Afridis are certainly a remarkable people; they have apparently quite accepted their position, quietly settled down, and ceased to molest us in the Khyber. The health of our troops still in the field continues to be good.

LIEUTENANT-GENERAL SIR GEORGE WHITE.

The late Commander-in-Chief in India, Sir George White, who had the misfortune to fracture his leg before leaving India, has not yet sufficiently recovered to take up the duties of Quartermaster-General of the Forces.

Surgeon Arthur R. Bankart, R N, has been appointed a Member of the Fourth Class of the Royal Victorian Order.

Correspondence.

"Audi alteram partem."

"THE DIPLOMA OF THE APOTHECARIES' SOCIETY."

To the Editors of THE LANCET.

SIRS,—The letter of Mr. Pope in THE LANCET of May 7th is so extraordinarily incorrect as to facts and issues that it must not be allowed to pass unchallenged. The statements in the letter may be summed up as follows. The action of the General Medical Council in prosecuting a certain L.S.A. Lond. for calling himself "Physician and Surgeon" is the outcome of the late election for a Direct Representative. Had a general practitioner been elected instead of Mr. Horsley the Council would, Mr. Pope suggests, have been prevented from carrying out such prosecution. I need hardly say that the conclusions at which Mr. Pope has arrived are entirely erroneous. The prosecution in question was decided upon long before Mr. Horsley's election and at the time when all the three Direct Representatives were general practitioners.

Further, to say, as Mr. Pope does, that our latest Direct Representative "has absolutely nothing in common with the general practitioner" is to make an assertion that could not be justified and one which I am sure would not be upheld by a dozen men in the whole profession. The result of the late election is in itself a striking proof of the inaccuracy of such a statement. It would be difficult, if not impossible, to find anyone in the whole profession who is more cognisant of the wants and cares of the general practitioner than Mr. Horsley. His many years' service as President of the Medical Defence Union made him daily and intimately acquainted with the troubles and dangers which surround them. For many years Mr. Horsley has worked hard in the interests of medical men generally, and to obtain for them their just rights and further protection of their practice and titles by amended legislation. He has spared neither money, valuable time, nor health and strength to ameliorate the condition of general practitioners, and whenever any action is being fought for true reform he is always found in the forefront of the battle. With regard to the unwisdom of the prosecution referred to by Mr. Pope I am sure all will agree, but he is entirely mistaken as to its origin and initiation.

I am, Sirs, yours faithfully,

A. GEORGE BATEMAN.

Devonshire-street, W., May 11th, 1898.

"PLAGUE MEASURES IN HONG-KONG."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 29th there is an annotation under the above heading in which apparently some of the Government officers are adversely criticised and, according to the writer, are presumed to be ignorant of the usual rules and regulations governing sanitation. After such a long interval it is possible that the subject will not be of much interest to your readers, but on the principle of hearing both sides of the question I trust you will see your way to publish a few remarks from one who has had eleven years' experience of the colony and most of it as assistant to the health officer of the port—more especially as your article has been published verbatim in the local newspapers. Quarantine, which incurs excessive expenditure and involves vexatious restrictions on shipping, is *per se* a relic of bygone days, and is, in my opinion, only justified when all the local conditions of each place are minutely studied and the amount of good to be derived therefrom thoroughly understood. The introduction of the recommendations of the Venice Conference *en masse* here at any rate and, I shrewdly suspect, in many other places, may well be characterised as "too ridiculous."

Hong-Kong is not, like London, a final port at which emigrants disembark and proceed to earn their living, but it is simply a port of call to which by far the larger majority come for a day or two only—some never even leaving the steamer—and then proceed on to their destination. We have the small number of 830,000 immigrants a year, or 2500 a day, to deal with, coming from places from six hours' to six days' distant and speaking every variety of dialect known and unknown to Chinese scholars. To medically inspect all these; to take the addresses of the various boarding-houses at which they are to stop—houses absolutely unknown to these ignorant coolies even after they have stopped there; to compel them to remain there until the incubation period of the disease has elapsed—which is what I take to be meant by "obtaining a guarantee that the individuals in question would remain at these addresses for a period sufficiently long to be placed under some supervision"; and to keep under observation those from a ship where a case of disease has actually occurred, seemed, and still seems, to me to be "too ridiculous" if not impossible. If this course was not recommended by the Venice Conference I am in error and quite mistaken as to the suggestions actually made. The staff of medical men, interpreters, and police required for this undertaking would be enormous and the delay and detention of vessels ruinous to all trade.

The recommendations of the Conference were to be undertaken to save the colony from small-pox, cholera, and plague. Small-pox is, as everyone knows or is presumed to know, an Eastern scourge and rages periodically all round Hong-Kong from Canton to Japan, and yet we have never had the least trouble in the way of an epidemic. Vaccination here is in full force with a Government vaccine institute and glycerinised lymph. Fifty cases (local and imported) in hospital at one time out of 250,000 inhabitants is the extent of a local epidemic. I only ask the writer to contrast this state of affairs with epidemics of this disease at home. Cholera epidemics are always prevalent in some place or other from Singapore to Shanghai and even in Japan. It is as an epidemic absolutely unknown here, thanks to our water-supply on which Government has lavishly and ungrudgingly spent millions, and the supply is now and has been for some time unequalled anywhere in the world. Plague was no doubt imported, but nothing short of the absolute intervention of Providence could have kept it out with our daily communication with China, on which we depend for our food-supply. It has come, and cases will crop up year by year as long as Chinese are Chinese, to a smaller extent in proportion as Government devote their attention to the proper housing of the natives and the sanitation of the town—far better objects on which to spend revenues than harassing shipping, which is all that quarantine ever does. I disclaim any idea of boasting, but one cannot well refrain from comparing the results of sanitary measures here carried out by various Government departments, as far as plague is concerned, with the results in India. Directly an epidemic occurs anywhere Government receives information from the consuls and medical officers at the various ports and is kept posted up to date on the subject. Bills of health are never looked at or even asked for in Hong-Kong.

I do not know what is meant by "England was forty years ago in the same position as Hong-Kong now is." As far as small-pox, vaccination, drainage, and water-supply are concerned, a great portion of England is fifty years behind this colony at the present time. Such

a state of affairs as existed at Gloucester, Maidstone, Richmond Asylum, &c., is an impossibility here. What we do and what we have done for the safety of the colony, long before the Venice Conference was ever heard of, is as follows: Whenever an epidemic breaks out in a port that port is declared infected and the governor in council may prohibit immigration and importation into this colony of all Chinese from the place infected; every vessel from thence is boarded and inspected—not by a custom-house officer (as I once saw done in London) but by a duly qualified medical man. If there are no cases of sickness the vessel is immediately released. If a case of disease exists it is promptly landed into an infectious hospital (which I venture to think compares not unfavourably with similar institutions elsewhere), the ship is disinfected and detained for twenty-four hours or longer at the discretion of the health officer of the port and if no further cases occur, released. This, I think, is absolutely sufficient and at any rate is all that is properly practicable with 2500 people a day to deal with.

I am afraid this letter is a very long one, but I for one take exception to a paper like THE LANCET inferring that this colony is behind the times in matters of sanitation, whereas in fact the responsible officers are men who in addition to professional knowledge bring also to bear on this subject a knowledge of local conditions and requirements of which the writer of the article in question seems absolutely ignorant. In conclusion, I would mention that we are so far behind England that the Government actually employs a qualified veterinary surgeon who daily inspects every animal slaughtered for food and every market in the place and I should much like to know in how many places in England such a very proper and very sanitary measure is carried out.

I am, Sirs, yours faithfully,

Medical Department, Hong-Kong, April 1st, 1898. J. BELL.

*** Whilst gladly printing the above letter we cannot pretend to agree with some of its contentions. The Venice Convention was not intended to apply merely to ports like London, but even as regards that port Mr. Bell describes conditions in Hong-Kong which agree in almost every detail with the arrival in this country of Russian and German transmigrants who passed through England to the United States during the cholera prevalence of 1892–95 and who were treated on exactly the lines which he describes as being "too ridiculous." Then again, Mr. Bell is correct, as he surmises he may be, in assigning to the Venice Convention a conclusion which finds no place in that treaty, but he is incorrect as to the diseases with which the Venice Conference had to do. It was solely concerned with plague. We are glad to endorse what he says as to the excellent sanitary work done in Hong-Kong and we know how ably the sanitary administration of the colony was utilised in the last outbreak of plague; but we hold that where such work and administration exist, the principles of the Venice Convention are adapted to deal with the introduction of such a disease as plague, although it is highly probable that they may need some modification in details.—ED. L.

"THE WALKING VALUE OF THE LESSER TOES OF THE HUMAN FOOT."

To the Editors of THE LANCET.

SIRS,—Permit me to say, with reference to Mr. Heather Bigg's quotation from "The Human Foot," that my test as to whether the toes are habitually used is a very simple one. Is the skin of the front part of the sole free from callosities? I cannot imagine this condition to exist if much walking be done, unless the toes collectively be used. When the toes are firmly pressed against the ground the long flexors, which are to the plantar arch as bowstrings or tie-rods, tend to include in it the heads of the metatarsal bones and so to uplift them. When these are borne down by the weight of the body the place of contact is determined by the position of the fixed toes; there is no sliding and therefore no friction. This advantage is of necessity lost when the tendons are attached to the heads of the metatarsal bones. Moreover, the extension of the base of support and the capacity to press on the ground all across the foot, even when the metatarso-phalangeal joints are bent, as in hill-climbing, must be of advantage, I, however, have not claimed for the smaller toes a "paramount value"; but I adhere most fully to my opinion that most people use them and that, in proportion as they are used, they are useful.

I am, Sirs, yours faithfully,

Gloucester, May 7th, 1898. T. S. ELLIS.

THE EARLY DIAGNOSIS OF MEASLES,

To the Editors of THE LANCET.

SIRS,—During the late epidemic of measles I have made one or two vain attempts to stop the spread of the disease by early isolation and have kept the other members of the family daily under observation from the time of their separation till they in turn fell ill. For a fortnight at least prior to the appearance of the influenza symptoms, although they seemed to be perfectly well and had a good appetite, the temperature persistently remained at 97°, but it at once commenced to rise directly the running of the nose and eyes commenced. I think that in cases where we are in doubt whether children have taken the infection or not this may be of service in helping us to come to a correct decision.

I am, Sirs, yours faithfully,

Surbiton, May 6th, 1898. F. P. ATKINSON.

"THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE CORPORATION DUTY."

To the Editors of THE LANCET.

SIRS,—Referring to your annotation on this subject, it is a matter of some regret that you have been unable to publish the case *in extenso*. The following extract may be of interest to some Members: "In delivering the judgment of the court in favour of the Crown Mr. Justice Wright said the section provided an exemption for property legally appropriated and applied for the promotion of science ..... On the authorities cited it could not be said that the property of the Royal College of Surgeons was legally appropriated and applied for the promotion of science at the time of the assessment. At the time of the original charter science might have been the main object, but the actual object at the present day was to be gathered from the later charters and the by-laws. *That object mainly was the granting of certificates or diplomas to persons desiring to become surgeons.* The balance-sheets showed that the largest source of income and expenditure was the examinations. The evidence brought before the court failed to show that the promotion of science was the main object."

The Council has always met proposals for reform or requests for the enforcement of certain by-laws with the stock argument that the College is a purely scientific institution and that its *sole* object is the promotion of the science and art of surgery. This fallacy has been exposed over and over again by Mr. Jonathan Hutchinson and others. The Council has, as we know, an immense respect for a judicial decision, especially when this is in its favour, as was the judgment in Steele *v.* Savory. We trust, therefore, that it will in future be kind enough to remember that the main object of the College as defined by a court of law is "the granting of diplomas to persons desiring to become surgeons," and that we shall hear no more of the "purely scientific" twaddle.

I am, Sirs, yours faithfully,

May 9th, 1898. W. G. DICKINSON.

PNEUMONIA, A MULTIPLE AFFECTION,

To the Editors of THE LANCET.

SIRS,—In a very interesting annotation on "Streptococcic Pneumonia," in THE LANCET of May 7th, p. 1275, you observe: "No attempt has been made in this country to differentiate what is ordinarily called 'pneumonia,' which is the name of a lesion and not of a disease, into the various diseases of which it may be a manifestation." That this is not correct will appear from a reference to a paper which I read before the Section of Medicine in the Royal Academy of Medicine in Ireland on Friday, Nov. 19th, 1897, on "Pneumonia, a Multiple Infection." An abstract of my paper was published in THE LANCET of Dec. 4th, 1897,

p. 1459. The paper itself was published in full in the *British Medical Journal* of Jan. 1st, 1898, and also in the *Dublin Journal of Medical Science* for January, 1898. I would ask you kindly to quote the two concluding paragraphs of the paper in question.

In conclusion, I venture to submit that there is clinical evidence to show that a true pneumonitis may occur in any one of the four diseases with which this communication deals—that is to say, erysipelas, influenza, tuberculosis, and enteric fever. Further, it is reasonable to suppose that in each case the pneumonitis is directly due to a localisation of the specific poison of the disease in the lung, whether that be a micro-organism itself or a toxin derived therefrom. Indeed, in respect of the four diseases named, the evidence, from a bacteriological standpoint, in favour of such a view is incontrovertible.

As regards enteric fever the influence of season and weather in determining pneumonic trouble is, no doubt, considerable; but it cannot be accepted as paramount or exclusive. And if it is objected that the bacilli typhi abdominalis of Eberth have not as yet been often found in the lungs or sputum of enteric fever patients I am justified in attributing this to the comparative infrequency with which, so far, search has been made for these bacteria in the pulmonary organs. Here, in any event, an almost untrodden path of investigation lies open to the adventurous footsteps and the keen perception of our Irish pathologists and students of bacteriology.

In my paper I show that the streptococcus pyogenes plays a part that is second to none in the production of influenza-pneumonia.—I am, Sirs, yours faithfully,

JOHN WILLIAM MOORE, M.D. Dub., F.R.C.P. Irel.

Fitzwilliam-square West, Dublin, May 7th, 1898.

THE DISTAL AERIAL CONVECTION OF SMALL-POX.

To the Editors of THE LANCET.

SIRS,—In your impression of April 9th attention is once more drawn to the question of distal aerial infection from small-pox hospitals, and it is evident that the last word has by no means been spoken on the subject. Since the theory of distal infection was first propounded by Mr. Power and adopted by the Local Government Board as a "good working hypothesis" it has been defended from attack with a persistence which is somewhat suggestive of a wavering faith.

There can be no doubt that a working hypothesis may be a very helpful thing, even though it may not be true; the atomic theory of light was such a one and it was superseded. "I began," said Harvey, "to think whether there might not be a motion in a circle"; that was his working hypothesis, but he did not stop there, for he proceeds to say, "this I afterwards found to be true," and that working hypothesis remains good to this day. Mr. Power and those who think with him have as yet attained the first stage only; they are thinking whether there may not be a motion in a circle, but they have not yet proved that it is so.

The recent case of Harrop *v.* the Corporation of Ossett (the *Times*, March 18th, 21st, and 23rd) shows this very clearly, for an experienced judge, after hearing such able exponents of the distal aerial theory as Mr. S. Murphy, Dr. Sinclair White, and Dr. Priestley, is not convinced, while the evidence of Dr. T. Orme Dudfield, Dr. Savill, and Dr. T. F. Ricketts serves to show that an influential body of the medical profession still finds difficulty in accepting the views so tenaciously upheld at Whitehall.

That a small-pox hospital in a poor and crowded locality may be, and usually is, a source of infection to the surrounding neighbourhood is not denied; it is when we come to inquire for the causes of the spread in its vicinity that doubt and difficulty arise, and it is impossible to agree with Dr. Priestley that so long as a small-pox hospital is allowed to be a source of danger, whether it be by aerial infection or by maladministration, it does not concern a medical officer of health as a matter of fact, for the question is not merely of academic interest, seeing that its solution must be of some importance, not as an argument for or against placing small-pox hospitals in crowded localities, but in view of the selection of a site within a mile of any human dwelling.

In every small-pox epidemic it is found that a certain percentage of cases around a hospital can be traced, apart from any question of maladministration, to ordinary known channels of infection, such as the incomings and outgoings of nurses, staff, tradesmen, patients, and friends of patients, and these are and must invariably be intensified as we approach such a centre as a small-pox hospital; but even after the most searching inquiry a residuum remains to which no clue has been discovered and of these it is said that they diminish in number as we get further from the hospital, which is not invariably the case, and that they are not in excess along the main approaches, which we should have no right to expect, for the people who walk in a street are not always those who dwell in it. The elimination of this residuum is always a matter of extreme difficulty, as has been shown by Dr. Orme Dudfield, Dr. Savill, and others, even when the investigation has taken place during the progress of an epidemic, much more after a lapse of weeks or months, yet it is upon the complete elimination of these cases that the theory of distal aerial infection is based. That the theory has never been disproved is no argument in its favour for the same might be said of the wonders worked by the diviner's rod. The main question is whether the theory fits in with the facts; if it does not, then it has not come to stay but must make way for some other that will. Facts, it may be said, are few, but if this is the case it would surely better become the Local Government Board to set in motion the wonderful machinery at its command for such inquiry in the public health service than to bolster up a theory in which few outside its own body will be found to believe. It is easy and sometimes convenient to treat matters of ten years ago as ancient history and as of little moment, but the fact remains that the discussion on the dangers of small-pox hospitals before the Society of Medical Officers of Health in 1885 is the most important one ever held on this subject and that the difficulties then suggested have never been met. The divergent views held as to the distance through which small-pox virus may be carried through the open air were well shown in the Report of the Hospital Commission and more recently in the Ossett case, but the point has never been settled even approximately, nor am I aware of any series of experiments with a view to its solution. Observations are wanted, especially in the country, where facts can be ascertained with much more precision than in a populous centre. There must be many available from medical officers of health and medical practitioners throughout the country if only they could be collected. The chief difficulty, however, in accepting the distal infection theory remains to be noticed—viz., the startling immunity which has over and over again been observed in large bodies of presumably susceptible individuals living near to small-pox hospitals and among whom, according to the distal aerial theory, small-pox should have appeared with an intensity proportioned to their nearness to the centre of infection. No explanation is offered for these remarkable exemptions from the incidence of a disease which (within limits still undefined) is acknowledged to be infectious above all others, and when it is borne in mind that by the chance discovery of its origin in a single case a clue might be given which would sweep away the better part or even the whole of the residuum on which the "circle argument" is based, the conclusion is irresistible that the theory of distal aerial infection rests on a very imperfect basis and that much more evidence is required before it can meet with general acceptance.

I am, Sirs, yours faithfully,

EDWARD T. WILSON, M.B. Oxon, F.R.C.P. Lond.

May 2nd, 1898.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Decline of Plague Mortality in Bombay.—Important Lecture by the Medical Officer of Health.—The Outbreak at Calcutta.—The Increase of Plague in Kurrachee.

THE past week has shown an improvement in the general mortality in Bombay, but there has not been a continuance of that rapid fall in the death-rate which gave so much hope the week previously. About 1200 deaths have been registered—still continuing more than double the normal number—a rate of about 75 per 1000 per annum.

A very able and suggestive lecture has been given on the Plague by Brigade-Surgeon-Lieutenant-Colonel T. S. Weir, the medical officer of health of Bombay. In the course of his address he laid down the following measures for scientifically resisting the disease: 1. Measures for the destruction or immunisation of rats or other carriers of the microbe. 2. Measures for the retreat or escape of the population from the area of invasion. 3. Measures for the immunisation or protection of the population against the

microbe. 4. Measures for the destruction of the microbe. He held that if the rat population could be destroyed or rendered immune in advance of the disease the spread of the disease might be stopped. The microbe would be starved. The simultaneous destruction of rats over a large area is very difficult, but it ought to be attempted. Brigade-Surgeon-Lieutenant-Colonel Weir states that in his opinion the influence of the rat is necessary for the occurrence and spread of an epidemic of plague and that the evidence shows that the disease is only slightly contagious and that something more than infection from sick to healthy human beings is required to explain the development and propagation of an epidemic. In this connexion may be mentioned a theory which has recently been started and which deserves further investigation. It is suggested that under normal conditions and endemically plague is a mild disease, but that under special conditions, such as by intensification in the rat, it develops into a virulent disease. It is also asserted that an epidemic of plague among human beings having subsided lingers as a mild glandular affection. These theories, however, were not touched upon in Brigade-Surgeon-Lieutenant-Colonel Weir's lecture. He holds that segregation of the healthy to be of any effect must be carried out in advance of the disease and on a large scale. There is little doubt that if a population could be moved away from an area in which plague had appeared and away from the line of migration of rats or other rodents it might be saved, but the population must be moved in advance of the disease. This may be possible in a moderate sized town or in a village, but it is not practicable in a large city like Bombay. He argues, therefore, how much cheaper, how much quicker, how much better, and how much easier to inoculate the people. Brigade-Surgeon-Lieutenant-Colonel Weir is a great supporter of M. Haffkine's prophylactic fluid for plague and he gave facts and figures which seem unanswerable. He further laid down two very important propositions: (1) that the simple glandular form of the disease is practically not infectious; and (2) that the organism of plague does not seem to be able to develop virulently or to survive where there are free currents of air. In the simple glandular form of the disease therefore he considers it is not necessary to remove the patient from a well-ventilated building. He criticised very severely some of the measures of the Plague Committee and stated that the measures were such that the living to escape detection almost ceased to call in medical men and that not 1 per cent. of the people who died had seen a medical man in their last illness. If some of the statements contained in this address can be corroborated by further investigations they will modify very considerably the measures to be adopted in future for plague epidemics.

The few cases which have been discovered in Calcutta have been instantly isolated, the "contacts" separated, and the infected buildings burnt or thoroughly disinfected.

In Kurrachee the disease seems to be increasing daily, 195 cases with 129 deaths having occurred up to date.

April 22nd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Salford and its Sewage.

AT the meeting of the Salford Council on May 4th Alderman Walmsley, M.R.C.S.Eng., J.P., stated that in July last a conference was held in the Salford Town Hall of representatives of the authorities in the watershed of the Irwell. 42 authorities intimated their willingness to send representatives and 67 persons, including members of the Salford Town Council, were present. The following motion was carried almost unanimously: "That in the opinion of this meeting of representatives of local authorities in the Irwell watershed the time has arrived when, owing to the advancement of scientific knowledge, it is no longer necessary or desirable that the Local Government Board should in all cases continue to insist on the disposal of sewage by land treatment." It was sent up to the Board, "but of course nothing had come of it." He thought that a step should now be taken and that a further conference should be held to formulate a plan which would either enable them to get an Act of Parliament or to compel the Local Government Board to alter its attitude on the land question. "The whole of the country was groaning under the condition laid down by the Local Government Board. The Salford Corporation had been tormented beyond measure over this business and so had the Manchester and other corporations." The Board seems to be a veritable Old Man of the Sea and the corporations so many poor Sinbads. Even in combination they are at present unable to shake themselves free.

Cottages for the Poor.

At the same meeting it was resolved to erect 36 cottages in King-street and Queen-street, the contract for which was £4678. It was stated that there was a strong feeling against tenement dwellings and so it was decided to build these cottages, each of which will have four rooms, 12 ft. by 12 ft., and the rent is to be 5*s.* 6*d.* a week. No doubt there will be a sufficient yard space and width of street, and if so there are many advantages on the side of separate dwellings over the ants'-nest sort of arrangement in what are sometimes called barrack dwellings. The destruction of cottage houses, partly on their merits and from the encroachment of railways and from various improvements, necessitate municipal action for making provision for the displaced population and this seems likely to become more extended in the future.

Manchester Sewage Again; Proposal to Revert to the Culvert Scheme.

At the meeting of the City Council held on May 4th Alderman Richards moved: "That the resolution passed on April 20th last in relation to the report of the Rivers Committee be rescinded and that the committee be instructed to revert to the culvert scheme." The City Council does not shine in the discussions on sewage disposal. There is a large amount of ignorant guessing as to estimates and the advocates of the culvert scheme have been captivated by its apparent simplicity. It is also a curious thing to see how difficult it seems to be for most of the chemically minded members of the council to see any good thing in the bacterial method, and this affection of the mind is not confined to the City Council, for no one has written more strongly against it than a deservedly eminent chemist from whom one would have expected something different. He blesses the culvert scheme, which is undoubtedly the outcome of chemical despair, or, to put it more accurately, of the despair of the chemical advisers of the Rivers Committee. It appears as if the chemical mind were unable to grasp the idea of vital action and was sceptical as to the enormous part it plays in the operations of nature. It would really be pitiful to go through the arguments adduced in favour of one scheme and against the other. But the matter is not yet settled and the discussion stands adjourned on the motion of Sir John Harwood.

Suggested Purchase of the Royal Infirmary Site.

A meeting of the special committee of the Manchester Corporation *re* the Royal Infirmary was held on May 9th and a resolution was moved by the Lord Mayor and carried unanimously to the effect that steps be taken to ascertain "if the trustees of the infirmary would be prepared to enter on the question of the disposal of the entire infirmary site." In January last the committee recommended the purchase of a portion of the site to be kept as an open space, leaving the shorn and mutilated infirmary building caged in the centre, at a cost of £286,000. This scheme fortunately fell through. During the discussions in the council hints were thrown out that if the whole of the site were obtained the infirmary might be removed altogether and on a portion of the land cleared a free reference library and a new art gallery might be built. In May last year the sub-committee, which has represented the infirmary trustees in the negotiations, suggested that the corporation should offer £550,000 for the whole of their land and buildings. The Corporation Committee said that they had no power to negotiate for the whole site and that they thought the price too high. Whether anything more than discussion will come from this move of the Corporation Committee the future will reveal. If, however, the present site of the infirmary cannot be extended sufficiently to allow of complete rebuilding on a liberal scale it would no doubt be the best solution of many difficulties for the infirmary to be taken elsewhere.

May 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Sir James Russell and the Plumbers' Registration Bill.

AT a public meeting held under the auspices of the District Council for Edinburgh and the East of Scotland for the National Registration of Plumbers at Edinburgh last week Sir James Russell said with regard to the Plumbers' Registration Bill that every effort would be made to have it passed through Parliament. It was, however, an unfortunate thing for the public health, not to speak of the plumbing craft, that its passage though Parliament was so difficult. Nothing but the general education of the public, he supposed, would ever lead to the passing of any Bill relating to public health.

Presentation.

On April 27th, in the Natural History Class-room, Marischal College, Dr. Alexander Brown, Lecturer on Zoology in the University of Aberdeen, was the recipient of a mahogany cabinet for microscopic slides. The gift bore the following inscription: "Presented to Alexander Brown, M.A., M.B., C.M., D.Sc., by his students in zoology on the occasion of his marriage. 14th April, 1898."

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal College of Surgeons in Ireland.

AT a meeting of the President, Vice-President, and Council held on May 3rd, the following were elected as examiners for the ensuing year:—Anatomy—Ambrose E. I. Birmingham and Alexander Fraser. Surgery—R. Glasgow Patteson and William Stoker. Physiology and Histology—Charles Coppinger and J. Alfred Scott. Biology—J. Alfred Scott. Pathology—Edward H. Taylor and Arthur Hamilton White. Midwifery and Gynæcology—Alfred J. Smith.—On May 6th the College addressed an important memorial to the Chief Secretary with reference to the provisions of the Local Government Bill so far as they affect the Fellows and Licentiates of the College and the members of the profession generally. In this document the opinion is strongly expressed that the existing system of election of poor-law medical—being also sanitary—officers is very unsatisfactory and the suggestion is made that all candidates for such appointments should be subjected to a previous competitive examination in which a knowledge of their special duty as medical officer or sanitary officer and as public vaccinator should be verified. Secondly, the College records its opinion that in the forthcoming Bill adequate provision should be made to enable Poor-law medical officers to retire upon a pension as a matter of right if incapacitated from duty by ill-health or after completion of the period of service required from civil servants. Thirdly, the College submits that the occasion afforded by this Bill should be availed of to improve the sanitary service in Ireland by providing adequate supervision by superintendent medical officers of health, each of whom should devote his whole time and attention to the sanitation of the group of dispensary districts committed to his care. It is to be hoped that this very important memorial will receive due attention from those responsible for the medical provisions of the forthcoming Bill. Anyone familiar with dispensary elections in Ireland will be aware that local influence—sometimes clerical—avails far more than the professional qualifications or previous medical career or personal merit of the candidate. As to the need for superannuation it is notorious that boards of guardians have frequently delayed to grant an allowance to an old or worn-out Poor-law medical officer until long after his services had ceased to be of adequate value to the poor of his district. Moreover, the principle of the new Government measure is to assimilate as far as possible matters of local government in Ireland to those which exist in England. It seems very desirable that the system of appointing superintendent medical officers of health which prevails in England should be extended to this country, where the local health officer is hampered and interfered with in his duties by the board of guardians of his narrow district, by whom he is appointed and on whom he is dependent.

Presentation to Sir William Stokes.

On Saturday, May 7th, at the Royal College of Surgeons in Ireland, Sir William Stokes, F.R.C.S. Irel., was presented with a set of plate in commemoration of the silver jubilee of his professorship of surgery in the College. An address, in which recognition of his professional and social qualities was most cordially expressed, was read and presented by Sir William Thomson, the President. The meeting, which was large and representative of the profession in Ireland, was addressed by Sir William Thomson, Sir George Duffey, the President of the Royal College of Physicians of Ireland, Sir Charles Cameron, and others.

Utilisation of the Union Infirmaries for the People.

It has been recognised on all hands that the passage of the new Local Government Bill affords an opportunity for pushing forward some of the many reforms so desirable in connexion with the system of management of the union infirmaries of Ireland. Dr. Smyth and Dr. Moorhead have recently called attention to the curious anomaly that all patients admitted to a union infirmary, even those who pay for their maintenance—and are glad to do so—are obliged first to enter the workhouse as paupers. The ban of pauperism is thus attached to the workhouse hospital and its inmates. Dr. Smyth in a letter dated March 31st proposed that these institutions should cease to be identified with the poorhouses, that they should be called "district hospitals," and that the sick poor who enter them should no longer be clad in the uniform of the pauper but be treated as ordinary hospital patients and required to contribute to their maintenance when able to do so. At a meeting of the Irish Workhouse Association held on April 23rd, presided over by Mr. Edmund Deare, D.L., and including the Countess of Fingall, Sir Francis Cruise, Sir Thornley Stoker, Sir George Duffey, Mr. Power Lalor, &c., the following resolutions were unanimously adopted:—

1. The workhouse hospitals shall henceforth be called district hospitals and the duties and powers of the guardians as regards such hospitals and the administrative control thereof shall be exercised through a committee of hospital governors appointed by the guardians, consisting either wholly or partly of members of their own body. The district hospital governors, subject to the general control of the Local Government Board and of the guardians, as regards finance may act without their acts being confirmed by the guardians and may appoint the officers of the district hospitals and regulate the expenditure.
2. That Lord Monteagle, Dr. Smyth, and Mr. John Dillon be requested to urge on the Government and on the Irish Members of Parliament the necessity of having the above amendment to Clause 23 of the Local Government Bill adopted.
3. That the Leaflet on Nursing be approved subject to amendments by Lord Monteagle and Sir Thornley Stoker, and that 3000 copies be printed, and that copies be sent to the clerk of the Poor-law Board, enclosing four for the chairman, doctor, clerk, head nurse.

The Belfast Union Infirmary.

At the weekly meeting of the Belfast Guardians on May 3rd the Local Government Board forwarded a letter for consideration. It was in the form of a complaint by a person who was for a considerable time an inmate in the infirmary and he gives his name and address. The system of pauper attendance is referred to in strong terms and it is alleged that a man of eighty years of age was "deliberately felled to the ground by a pauper attendant without the slightest provocation." The pauper barber who was appointed to shave the patients was subject to "epilepsy and when seized with a fit while shaving a patient usually left his mark behind him." The communication further drew attention to a system of blackmailing which, it was stated, was carried on by pauper attendants, the want of regulations which permitted the paupers stealing rations from the infirmary and hospital patients, the unsanitary condition of the wards and draughts in the corridors, and the lack of proper supervision, which the writer said rendered the infirmary a pandemonium instead of a place for sick persons. "In short," the letter said, "the man or woman who has no money gets no attendance here." A committee was appointed to consider this letter.

The Ulster Medical Society.

At the meeting of this society held on the 5th inst. Dr. Lowry, an old Belfast student who has for several years lived in different parts of China, read a paper on Some Notes on Tropical Diseases and Bubonic Plague taken during a residence in China, 1881–1896. Dr. E. C. Bigger opened a discussion and read a short paper upon Some of the Principal Points in the Treatment of Typhoid Fever. The President (Dr. Lindsay) having read notes on a case of Hyperpyrexia during an attack of Typhoid Fever, an

interesting discussion followed the reading of the various communications.

Belfast District Lunatic Asylum.

Mr. S. Graham, assistant medical officer of the Belfast Asylum, who has been in charge of the Purdysburn Branch, has resigned on his being appointed resident medical superintendent of the new County Antrim Asylum.

Success of a Belfast Student at Cambridge.

Dr. W. Hanna, a former distinguished student of Queen's College, Belfast, at the recent examinations held by the State Medicine Syndicate of Cambridge University for the Diploma in Public Health, obtained first place in bacteriology.

Skin Grafting.

AT the meeting of the Academy of Sciences held on May 2nd M. Ollier remarked that it had long been the custom since the experiments of Reverdin to hasten the healing of wounds by grafting small pieces of skin on to the raw surface. But according to M. Ollier it is quite possible to employ large grafts containing 20, 30, or even 40 square centimetres by the use of which the wound heals without showing any cicatricial characters, the skin preserving its natural appearance. M. Ollier cited as an example of this treatment the case of a patient living near Lyons who was treated by this method for an extensive burn on the inner aspect of the leg. The injury had occurred many years previously and the wound had assumed a malignant aspect, so that amputation of the leg had been advised. After the site of the wound had been carefully scraped and cleansed eight grafts, containing from 20 to 25 centimetres of skin respectively, were applied. All the grafts took and at the end of some weeks the raw surface was replaced by real skin containing sweat-glands and hairs and in every way similar to normal skin. M. Ollier was struck by one thing, namely, the apparent increase in the size of the grafts during the course of the healing of the wound, whereas it is well known that they generally shrink. He attributed the apparent growth to the mobility of the neighbouring parts, a mobility which caused *tiraillments* in every sense.

Radiography as a Means of Certifying the Existence of Death.

At the meeting of the Biological Society held on April 23rd, M. Bougarde showed three photographs of the thorax, two of them from living persons and the third from a corpse, all taken by the x-rays. In the two first the different thoracic organs and the walls of the thorax itself exhibited a hazy outline, so that their limits could not be exactly made out. This, of course, was owing to the natural movements of the parts, the pulsations of the heart and the great vessels, and the movements of the diaphragm. Even when the subjects held their breath so as to minimise movement as much as possible the outlines were still hazy and the outline of the diaphragm was seen as a shadow varying in depth and extending over the ninth and tenth intercostal spaces. The heart and great vessels were seen to occupy the centre of the chest as a dark oval mass, the shadow of which was dense in the centre and gradually faded away towards the periphery until the almost transparent lungs were reached. In the radiograph of the corpse, however, the appearance was quite different, for all the organs had sharp and well-defined edges.

The General Association of French Medical Practitioners.

The General Association of French Medical Practitioners has just held a meeting in Paris at which several provincial delegates proposed resolutions on behalf of the various bodies which they represented. The Société de la Gironde recommended that in each Faculty instruction should be given both in medical ethics and in the departments of law which have a bearing on medical practice. The Société de la Sarthe recommended that foreign medical men who had become naturalised should be required to serve in the army, the idea being that all medical men desiring to practise ought to be subject to the same military obligations, whether they be French by birth or by naturalisation, without any special exemption for the latter. Some recommendations made by the Society of Melun, Fontainebleau, and Provins and the Society of Algeria opened up questions of reciprocity and led to a comparison of the privileges accorded on the one hand to foreign medical men practising in France, and on the other hand to French medical men practising in foreign countries. Eventually a resolution was adopted to the effect that *la faculté d'émarger aux budgets départementaux ou communaux* should be granted to foreign medical men only under exceptional circumstances. The Society of Vaucluse recommended that medical students should not serve in the army until the completion of their curriculum and that they should pass a year as officers of the Army Medical Department; a concession on similar lines was also recommended for pupils of the École Centrale des Arts et Manufactures. Finally, the Société de la Gironde recommended that the university degree of Doctor should not carry with it the right to practise medicine, but that doctors of medicine of French nationality who had not been found guilty of any offence should have this right conferred on them by a jury of medical men not belonging to any teaching staff and presided over by a professor of the Faculty. The scope of the examinations conducted by this jury ought to include practical knowledge, the state of the law in relation to medicine, and medical ethics.

The Prophylaxis of Tuberculosis.

At the meeting of the Academy of Medicine held on May 3rd, M. Grancher read a report on the prophylaxis of tuberculosis, of which the following is a summary:—1. The Academy hereby confirms the resolutions arrived at in 1890 which advised the following three measures of prophylaxis: (α) all sputum should be collected in a pocket spittoon or some vessel containing solution of carbolic acid of a strength of 5 per cent. or else a little water; (β) to do away with sweeping for the removal of dust and to replace it as far as possible by washing or rubbing over with a damp cloth; and (γ) to boil all milk before drinking it, whatever be its source. 2. With reference to family practice the Academy recommends to all medical men the continued application of these prophylactic measures from the time when tuberculosis is diagnosed, and also, if possible, to keep the disease quiescent by means of an early diagnosis and proper treatment. 3. With regard to the army the Academy suggests that early cases of tuberculosis in which the expectoration does not contain bacilli should be invalided temporarily, and permanently as soon as the sputa are found to contain Koch's bacilli. The Academy makes an appeal for the earnest coöperation of the military and hygienic authorities to see that the three measures above announced are carried out in every barrack. 4. In the case of schools, workshops, shops, &c., which have to be reached through the medium of those in charge, the Academy can only ask them to consider very earnestly the importance of these hygienic questions and the very simple and easy methods which are quite sufficient to carry out a real prophylaxis against the extension of tuberculosis. 5. The Academy approves of the conclusions which the commission appointed to examine into this question with regard to hospitals arrived at—that is to say (α) all tuberculous patients shall be isolated in separate wards until separate sanatoria can be provided for them; (β) antisepsis shall be carried out both in the tuberculous ward and the general ward, especially by careful cleansing of the floors and the substitution of washing for sweeping; (γ) the health of the general staff should be improved by giving higher wages, by drawing them from a better class, and by the grant of retiring pensions; and (δ) a staff of hospital sanitary officers ought to be formed. 6. The Academy approves of the restrictions laid down in the proposed Bill and of the new regulations with regard to meat taken from tuberculous animals. Seizure and total destruction of this kind of meat will only be employed in those cases, which are not very common, of general tuberculosis and "fevered" meat. The use of tuberculin is strongly recommended to breeders and the elimination from the herd by means of the butcher of those animals which only react slightly. 7. The Academy, wishing to mark the exceptional interest which it takes in seeing the prophylactic measures against tuberculosis carried out continuously, has appointed a new and permanent commission under the name of the Commission of Prophylaxis against Tuberculosis, which will have for its objects the encouragement of, and coöperation with, any effort which may be made against the dissemination of the tubercle bacillus.

May 9th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Antitoxic Serum of Typhoid Fever.

TYPHOID fever of late years has occupied the attention of Italian physicians in proportion as the water-supply has proved less and less adequate to the increasing population, and even outside the profession, in Parliament itself, the "interpellations" addressed to the Minister of the Interior by deputies whose constituencies are scourged by that "Nemesis of impure drinking water" multiply in frequency from session to session. Signor Arcoleo, under-secretary for that department, was, for instance, on April 25th interrogated by the member for Paternopoli (Signor Del Balzo) as to whether anything was being done in view of the approaching summer to prevent another "invasion of ileo-typhoid" due to "acque potabili" which were "deplorably polluted." I mention this to explain the exceptional interest taken by the Italian delegates at the Madrid Congress in the memoir on the "Antitoxic Serum of Typhoid" read by Dr. Chantemesse, Professor of Pathology, Experimental and Comparative, in the University of Paris. That serum (it is claimed by its discoverer) "has given the best results in patients suffering from typhoid, diminishing rapidly the grave effects of the nervous phenomena, lowering the temperature and accelerating powerfully the recuperative process." In last January Dr. Chantemesse by experiments on domestic animals, especially rabbits, succeeded in isolating the microbe of the fever from which he obtained a toxin finally shown at its best by "cultivating highly virulent typhoid bacilli in a solution of peptone." After five or six days from the beginning of the culture the toxin appears in abundance, but gradually declines, so that no time can be lost in preparing from it the antitoxic serum—a preparation effected on analogous lines to that of the anti-diphtheritic serum. Within from four to five hours (says Dr. Chantemesse) after the typhoid bacillus had been in deadly quantities injected into the blood of several rabbits an injection of one-fourth of a cubic centimetre of the antitoxic serum so far controlled the fever as to "put it in full defervescence" by next day. Animals differ in their response to the serum; but in none of them under Dr. Chantemesse's treatment has the result been absolutely negative. Meanwhile, his experiments are in process of being checked at the various clinical schools throughout the kingdom and in the course of the autumn we are promised a number of independent and detailed reports as to their outcome.

May 1st.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

British Troops in the Soudan.

THOUGH the telegraph wires flashed the news of the Atbara victory on April 8th in one hour to Cairo there has not yet been time for detailed written despatches to reach us from the hard-worked medical officers at the front. Daily messages are received at headquarters reporting the condition of the sick and wounded, announcing operations, and deaths, sometimes mentioning deaths. The bulk of the wounded are still at Ginanetti, but it is hoped that the first convoy northwards will start from there in a few days. Two slightly wounded colonels have already reached Cairo with the newspaper correspondents and one lady has been invited to proceed to Wady Halfa to meet her wounded husband there. There are to-day 63 wounded at Ginanetti and at Assouan. The sick returns kindly furnished me by the authorities are as follows:—Ginanetti 39, Darmali 90, Atbara 20, Wady Halfa 10, and Assouan 3. This gives a total of 162 sick, or rather more than 4 per cent. of the total strength of 3800 men. This compares quite favourably with the sick-rate of 6 per cent. in Cairo, which includes, as usual, much venereal disease. The sick-rate of the British troops before the "spoiling for the fight" was only 1 per cent. During the last week there have been 3 deaths at Ginanetti from dysentery, 3 deaths from enteric fever, and there are now seven seriously ill from the effects of that constant follower of the British army. It is satisfactory to know that enteric fever is now very rare in Alexandria, where Berkefeld filters have been provided for about two years; the disease is much less common in Cairo than it was before the introduction of efficient filters, and now for the first time an attempt has been made to supply an army in the Soudan with Berkefeld filters. The Royal Engineers have been busy this winter in preparing some metal cases for two groups each of Berkefeld candles. The case resembles in shape and weight a mountain gun and can easily be carried by one mule. The filters work by a hand pump and will turn muddy water into clean water in a few minutes. If both ends of the case work simultaneously speed is greater and less force is required, or if desired one end alone can be worked while the other is being cleaned. There is no doubt about the practical utility of this new method of utilising the Berkefeld filter as a mechanical filter, but of course every machine must be tested independently by a bacteriologist before it can be thoroughly recommended. Then will come the great practical difficulty of all these filters—how and when to render them sterile. These new filters cannot have arrived in time for the Atbara battle, for they were late in starting and were somewhat delayed in transit.

Plague at Jeddah.

The Superior Council of Health of Constantinople early this month sent a commission of three members to Jeddah to decide whether there was or was not any plague there. The two younger members, Dr. Fuad Bey, a Turk, and Dr. Nicolaides, a Greek, were chiefly occupied in surveying the disembarkation of pilgrims outside Jeddah. The Greek head of the mission, Dr. Cozzonis, very kindly allowed Dr. Bittar of the Egyptian Sanitary Department to pay a short visit to Jeddah with him. Every facility was shown him by Dr. Zantopolidis, the Greek Director of the Sanitary Office at Jeddah, who is a young, active and very intelligent official. The town of Jeddah, walled in with its five gates, can now boast of clean streets and large airy houses with windows of open lattice work instead of glass. But the 20,000 inhabitants are far from content, for they live by the pilgrimage, and this year the Turkish Government has decreed that the pilgrims shall not enter the city. A military cordon surrounds the pilgrim camp, which is about ten miles from Jeddah, but as there are no tents—the pilgrims being exposed to the fierce sun while waiting for camels or steamers—and as all food and water has to be brought to the camp from Jeddah, it is evident that there are already several causes provided for future disturbance. Unlike the previous experience of Egyptian Commissioners the Jeddah natives showed none of the fright evinced by both Hindoos and Mussulmans in Bombay. Another difference was that whereas in Bombay it was almost impossible to obtain rats or mice there were plenty forthcoming in Jeddah, and some of those found dying in the streets contained plague bacilli. There is a plague hospital in Jeddah, but it contained only one patient, an Indian without friends or money. Dr. Bittar described him as a typical septicæmic case with great enlargement of the right inguinal glands surrounded by œdematous tissue. He had great prostration, a typical tongue, a temperature of 106·7° F., a pulse of 140, and was evidently dying from plague. No necropsy was possible, but the microscope and cultures revealed plague bacilli in the inguinal glands. Two other men were convalescing from plague and buboes, but all these three were residents of Jeddah. There seems to be no evidence yet that plague has been imported this year from India or elsewhere. On the contrary, everything points to its being a recrudescence on the spot of last year's infection by stored-up rags. From March 21st to April 16th of this year 36 deaths from plague have been officially returned. If to this number we add unknown cases among women whose bodies cannot be examined and deaths returned as pneumonia we can guess that there have perhaps been 100 cases.

Cairo, April 27th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The After-care of the Insane.

A COMMITTEE of the Neurological Association recently sent a circular-letter to alienists and superintendents of hospitals for the insane for the purpose of inquiring as to the necessity for after-care of the insane. The result of

this inquiry is as follows. Fifty replies were received. Of the entire number of correspondents only 6 are either doubtful of the desirability and practicability of after-care associations for the dependent insane or are decidedly opposed to such a step. The reasons given by them are that the number of cases which are likely to be benefited by such aid is too small to be advisable, that while such a project might be desirable it is inexpedient, that while excellent in theory it would be impossible in practice, &c. On the other hand, the overwhelming majority of 44 in 50 (or 47 in 53 if the committee be included) express, and in not a few instances in the strongest terms, their decided belief in the great advantages likely to result from properly organised and conducted aid societies of this kind for discharged insane patients who are recovered, convalescent, or improved. Regarding the number likely to be benefited in this way the experience of superintendents of hospitals for the insane, as indicated in these replies, is not of much assistance, as the few who replied found it difficult to properly estimate the number of deserving patients. As to the auspices under which such associations should be conducted it is the general opinion of both the alienists and neurologists that they should by all means be begun as private organisations and so continued until their utility be demonstrated. If successful, State aid could then probably be obtained. In reply to the question regarding the advisability of establishing State homes for convalescent patients as a part of the general policy of States toward their insane there is more diversity of opinion, but the same degree of interest and careful consideration of the subject. Scarcely a member of this association has written in opposition, and of 29 hospital superintendents and other alienists 19 were warmly in favour of such an accessory provision, 5 were doubtful of its expediency, and 5 were decidedly opposed to the project. Of 4 members of lunacy and charity boards 1 is in doubt as to its utility and the rest think it would be an unnecessary and useless experiment. As a result of their inquiries the committee reports the following conclusion: It is the general and well-nigh unanimous sentiment of those who are the most conversant with the needs of the insane in this country that measures should speedily be inaugurated for the temporary relief of discharged, recovered, convalescent, and improved insane patients of the dependent class by organised outside assistance.

The New York Skin and Cancer Hospital.

At the opening of the new building Dr. Bulkley, the originator of the hospital and its present secretary, delivered an address devoted to the history of the undertaking. The first patient was admitted to the old building in Thirty-fourth-street on Feb. 26th, 1883. During these fifteen years the hospital has received about $375,000, of which $75,000 came from the board of patients and sale of drugs in the dispensary. The land and building are now practically free from debt. Since the opening of the hospital 25,031 cases have been treated, 3010 of which were in the cancer department. The greater number of patients were out-patients and the total number of visits was 118,154. The number of prescriptions filled by hospital druggists was 132,263. In the wards of the hospital there had been 2872 patients and the total number of hospital days was 165,077, of which 117,658 were free.

Railroad Accidents.

It appears from the Inter-State Commerce Commission's statistics of the casualties to persons in railroad accidents in the United States for the year ending June 30th, 1896, that the total of killed was 6448; of injured, 38,687. For nine years the average deaths were 6444 a year; the average injuries were 33,000. Of actual passengers the killed in nine years averaged 283 a year and the injured averaged 2600. The passengers killed were only one-twenty-third of all the deaths and passengers contributed only about one-thirteenth of the injured. Of all the casualties to passengers less than one-half are in train accidents. The other deaths and injuries to passengers occur at highway crossings (going to and from stations), at stations, and from other causes. The last item includes those killed and injured while getting on and off moving trains, falling between cars, sticking their arms and heads out of the windows, and in other exhibitions of carelessness. In one State the passengers killed and injured from causes beyond their own control have, for at least ten years, been less than half the total. Of the injuries much the greater part are very slight, a large percentage being so slight that even the lawyers can find in them no basis for damage suits. It may be safely said, therefore, that the railroads are responsible each year for the death of only 142 passengers and for the injury of only 1300. The passengers killed in a year are 283. But the passenger travel in 1896 was 13,049,000,000 miles, or it equalled one passenger travelling that distance. It follows that a man can travel by rail 46,000,000 miles before he is killed. In other words, if he travels night and day at 35 miles an hour he must travel 150 years before he is killed. But if the average deaths are 6444 a year and the passengers killed are but 283, if the average injuries are 33,000 and the passengers injured are but 2600, how shall we account for the other 6161 killed and 30,400 wounded? To save a confusion of figures I shall deal only with the killed henceforward; the lesson will be precisely the same as if it included the wounded also. The employés killed per year in the last nine years were 2210 and the other persons were 3951. Of the employés killed last year about 12 per cent. were killed while coupling and uncoupling trains, 25 per cent. by falling from trains and engines, 19 per cent. in train accidents, nearly 10 per cent. from overhead obstructions at highway crossings and at stations, and, finally, 34 per cent. from other causes. A very large percentage of the deaths is classified so vaguely as to vitiate analyses or deductions, but the small percentage due to train accidents is striking and extremely interesting as suggesting the safety with which trains are run. The total number of employés in the year considered was 826,620. These men did an immense amount of travelling, but those killed in train accidents were only 348, and, of course, most of these were in freight train accidents. There still remain 3951 deaths per year to account for, or 61 per cent. of the whole. These are neither passengers nor employés. Of the 3951 persons other than passengers and employés killed every year (being 61 per cent. of all the deaths) 3566, or 55 per cent. of the total or 90 per cent. of the others, are trespassers. Nearly 10 persons are killed every day in the year because they are where they have no right to be. Of these trespassers 141 are killed at highway crossings, 323 at stations, and 2957 from other causes. The trespassers are run down in small numbers at road crossings, in greater numbers at stations and in yards, and in still greater numbers out in the open road, and this shocking waste of life is going on, not through the fault of railroad officers, but because of an ignorant and apathetic public opinion.

April 19th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Dengue Fever in Queensland.

Two interesting papers on Dengue Fever have been published simultaneously—one, by Dr. Hirschfeld, in the *Inter-colonial Medical Journal* for March, deals with the epidemic in Southern Queensland; the other, by Dr. F. C. Hare, in the *Australasian Medical Gazette* for the same month, describes the disease as observed in Northern Queensland. Both writers agree as to the intense infectivity of the disease. According to Dr. Hirschfeld the period of incubation is about two weeks. Dr. Hare says "there is plenty of evidence to show that the incubation period does not extend beyond one week." Dr. Hirschfeld states that "infection can take place despite unfavourable conditions of climate and soil and locality," but that "where climatic and local conditions are unfavourable a further spread of the disease is rendered unlikely." It is quite likely to invade the southern colonies. In the opinion of Dr. Hare the disease is essentially tropical and is greatly influenced by temperature. The district of Herberton was exempt from the disease owing probably to its altitude and comparatively cold climate. As to immunity Dr. Hare maintains that it does not extend beyond two years after an attack, large numbers being attacked who had gone through the disease two years previously; a few cases had an attack every year. Dr. Hirschfeld admits that it is not possible to speak with final definiteness as to immunity, but so far it has been found that a patient who has once suffered from the fever will not be attacked by it a second time. When patients make statements to the contrary a close examination will reveal that the supposed former attack was not accompanied by a rash, without which the diagnosis

of dengue is not complete, and was probably influenza or a gastric attack. Both writers agree fairly as regards symptomatology, sudden onset, pains, and rash. Dr. Hare says that the pulse presents no striking peculiarities, but Dr. Hirschfeld maintains that the pulse-rate does not run parallel to the temperature and "it is characteristic of dengue that a relative bradycardia may be observed during the continuance of the fever" and an absolute bradycardia frequently appears during convalescence. Both agree that the main element in treatment is rest. Dr. Hirschfeld thinks that the exhibition of quinine from the first diminished the tendency to relapse. For hyperpyrexia he advocates lactophenin. As bearing out Dr. Hirschfeld's views as to the probability of dengue spreading to the southern colonies Dr. Casement of Kempsey, New South Wales, has made a report to the Board of Health concerning an outbreak of dengue in that town, where a great many cases have occurred, and he supposes that the disease was introduced from Queensland.

Appointment of Health Officers under the New Health Act, New South Wales.

The Government of New South Wales, acting on the recommendation of the Board of Health, has appointed two medical officers of health—one for Sydney and its neighbourhood, constituting the metropolitan combined districts; the other for Newcastle and the towns on the Hunter River, to be known as the Hunter River combined districts. The appointments are made under the new Public Health Act and though the salaries are paid by the Government the new officers are really to be attached to the municipalities, to whom they will send in regular reports. The duties attached to the positions are practically to bring the provisions of the new Act into operation in the districts named, which include about 45 per cent. of the population of the colony, and gradually to familiarise the public with the provisions of the Act. Dr. William George Armstrong has been appointed to the metropolitan district at a salary of £750 a year and Dr. Robert Dick to the Hunter River district at a salary of £700 a year. Both gentlemen are graduates of Sydney University and subsequently obtained the diploma of public health at Cambridge.

Death of a Medical Man through the Mistake of a Druggist.

On March 7th Mr. Samuel Prince Williams, L.R.C.P. and S. Edin., of Nicholson-street, Fitzroy (a suburb of Melbourne) called at a druggist's shop and asked for a solution of sulphate of morphine for hypodermic injection. The solution was made up by the son of the proprietor of the shop. Mr. Williams drove on to see a patient, whom he injected with the solution. It appears that he was accustomed to use morphia himself and after injecting the patient he gave himself an injection also. He then drove home with his wife. Before they had gone very far he was seized with violent convulsions and pain. Mr. Williams recognised that some mistake had occurred and drove to a neighbouring practitioner's house, arriving in a collapsed condition. He was found to be evidently suffering from the effects of atropine. He rallied somewhat, but died the next morning. His patient was affected with similar symptoms, but not so severely, and fortunately recovered. The mistake arose through the druggist keeping morphine sulphate and atropine sulphate in similar bottles with written labels and the dispenser had taken up the wrong bottle, Mr. Williams being in a hurry and telling him to be quick. The dispenser was committed for trial for manslaughter by the coroner.

Death of a Child from Swallowing a Bone: Alleged Neglect by Hospital Authorities.

On March 23rd the deputy coroner for Sydney held an inquiry concerning the death of a child at the Children's Hospital on March 19th. It appeared that while the father was feeding him with a spoon with some Irish stew the child began to choke and cough. He took the child to a druggist, who examined him, said that he had a bone stuck in the throat and advised the removal of the child to the Sydney Hospital. There after some little delay, Dr. Bowker, resident medical officer, examined him, but could feel no bone, and Dr. Harris, senior resident, failed also to detect the bone. The child had no difficulty of breathing. The father was told to take the child back. Instead of doing so he took him to the Prince Alfred Hospital, where he was examined by the resident on duty, by the medical superintendent, and Dr. McCormack, honorary surgeon. All failed to discover the bone. Dr. McCormack ordered the child to be kept in the hospital and an x ray photograph to be taken. The parents took the child out and had an x ray photograph taken themselves, but it did not reveal the position of the bone. The child got much worse and they took him to the Children's Hospital, where an operation was performed. While the trachea was being opened the child stopped breathing and in spite of artificial respiration and treatment died. Dr. Chisholm, honorary surgeon, said that the cause of death was septicæmia following an abscess round a piece of mutton bone which had perforated the gullet a good way down. The finding of the coroner was that the treatment adopted was proper and that the deceased died from a bone being accidentally embedded in the throat, accelerated by a necessary surgical operation under chloroform. The coroner said the case should have been reported by the authorities at the Children's Hospital and no certificate should have been given. He thought that if the parents had taken the child back to the Sydney Hospital at once his life might possibly have been saved, but that was problematical.

Thirlmere Home for Consumption.

Some seventeen years ago the munificence and philanthropy of a private citizen, Mr. Goodlet, established the Thirlmere Home for advanced cases of phthisis in destitute circumstances. Mr. Goodlet not only established, but for many years maintained, this most excellent institution. When the financial crisis came he found himself unable to continue his work and he handed the home over to the public with an appeal to the charitable to maintain it. For a time the public responded, but the subscriptions have gradually fallen off until the institution can no longer be maintained. At the Jubilee time the public subscribed £12,000 for the Queen Victoria Consumption Hospital and apparently thought it had then done enough for the phthisical patient. Now that attention has been drawn to the matter by the press the public will assuredly keep the Thirlmere Institution going.

St. Vincent's Hospital, Melbourne.

A public meeting was recently held in Melbourne, his Excellency the Acting Governor in the chair, to raise funds for the extension of St. Vincent's Hospital. The project was approved by the meeting and £2000 were subscribed for the purpose.

April 1st.

Obituary.

JAMES RHODES, M.R.C.S. ENG., L.S.A.

ON April 21st one of the best known inhabitants of Glossop passed away in the person of Mr. James Rhodes. He was born at Tintwistle, near Glossop, in 1830 and was apprenticed to the late Dr. Turton at Glossop in 1849. After attending lectures at the Pine-street School of Medicine in Manchester he took the Licence of the Society of Apothecaries of London in 1853 and the Membership of the Royal College of Surgeons of England in 1854, when he began to practise at Glossop. He was thus associated with Glossop all his life. He was the first medical officer of health of the Glossop borough and district, honorary surgeon to Wood's Hospital, Glossop, and held various other local appointments. Mr. Rhodes had an extensive private practice and worked hard at his profession, but found time to devote to scientific and philosophic subjects. He was a member of the Manchester Literary and Philosophical Society and a justice of the peace for the borough. The respect in which he was held was evidenced by the large number of borough officials, representatives of societies, and personal friends who followed his remains to the grave.

BORIC ACID IN BUTTER.—At Pontypool police-court on April 23rd a grocer of Garndiffaith was fined £5, including costs, for selling butter adulterated with boric acid. The county analyst said that the sample contained 91 grains of boric acid to the pound; he had examined over 400 samples of articles for boric acid, but the highest percentage he had observed previously to this case was 63 grains to the pound.

UNIVERSITY OF CAMBRIDGE.—**The following candidates have satisfied the examiners in both parts of the Examination in State Medicine :—**

H. W. L. Barlow, O. Beven, H. L. Billett, J. J. Boyd, J. Brownlee, C. E. Corlette, W. E. Dixon, O. Eaton, W. M. Eaton, T. A. Ellwood, W. Hanna, A. Hudson, H. E. R. James, W. H. Jewell, A. E. Larking, W. J. Lubeck, R. P. Mackenzie (Joh.), E. J. Moore, B. N. Mullan, R. W. C. Pierce, A. E. Roberts, E. Robertson, A. Sheppard, A. C. Turner, and S. Worthington.

UNIVERSITY OF EDINBURGH.—**The following is the official list of candidates for degrees in Medicine and Surgery who have completed the first, second, and third professional examinations respectively this spring :—**

First Professional Examination.—May Agnew, W. L. L. Alston, James Arthur, A. W. Atkinson, A. K. Baxter, A. W. Beveridge, Henry Beveridge, William Black (with distinction), M. N. Bose, C. H. Bösenberg, J. R. Bosman, J. O. Boyd, F. H. Bridgman, James Brocket, R. D. Brown, D. G. Carmichael, Adam Clark, C. E. Clay, A. P. Coskey, D. M. Crooks, W. J. Crow, T. M. Cuthbert, N. S. Cuthbertson, F. I. Dawson, W. H. Elder, S. A. Ellerbek (with distinction), A. P. R. Fennell, N. C. Fischer, Stephen Garvin, Sidney Gilford, J. M. Glasse, R. A. Glegg, Wilbert Goodchild, R. M. Grant, H. W. Gush, F. M. Harper, Arthur Hutley, R. C. Irvine, Isaac Ivey, Bertha Jex-Blake, Edward Johnston, A. R Khan, James Kirkwood, P. V. Langmore, Abraham Leach, A. B. Leakey, J. G. M'Caughey, R. J. M'Clelland, F. D. S. Mackenzie, M. E. Mackenzie, Daniel Mackinnon, T. H. Mackinnon, William M'Lachlan, R. P. M'Neil, D. M. Macrae, J. B. Mason, J. K. Matheson, Paul Mathews, Robert Morison, D. N. W. Murray, Robert Murray, E. G. O. Nixon, A. C. Owen, J. L. Palmer, Sophie Palmer, John Politachi, E. T. Potts, E. C. Prichard, H. St. J. Randell, F. L. Rigby, W. A. Robinson (B.A., B Sc.), T. W. H. Ross, A. J. Rowan, C. J. Shaw, Kate Southon, W. C. Speirs, D. A. Stewart (M.A.), W. H. Swaffield, J. M. Taylor, G. C. Trotter, B. P. Watson (with distinction), John Wier, Ada Wilkinson, and David Young.

Second Professional Examination.—T. H. W. Alexander, J. D. Anderson, H. E Arbuckle, S. A. Ballantyne, J. W. Barrack, M. C. Beatty, A. L. Bennett, J. M. Benson, C. A. Bentley, Hubert Bishop, A. B. Black, J. A. Black, J. S. Bostock, J. B. Boyd, O. C. Bradley, L. P. Brassey, J. M. L. Brown (M.A.), Adam Brydon, G. F. Buist, P. C. Campariole, Malcolm Campbell (M.A.), G. S. Carmichael (with distinction), Kirkland Chapel, C. S. Clark, H. E. Coghlan, V. A. P. Coghill, W. P. Cormack, John Craig, T. A. Davies, S. L. Dawkins, W. I. Dunn, William Eadie, J. S. Enslin, D. J. Fergusson, D. C. L. Fitzwilliams, Andrew Fleming, J. G. Forsyth, Alexander Frew, W. E. Frost (with distinction), J. S. Geikie, William Girdwood, Thomas Graham, St. L. H. Gribben, G. W. Guthrie, F. S. Haldane, G. H. Hannah, N. E. J. Harding, Herbert Harris, W. E. Herbert, Davis Heron, H. O. Hobson, K. W. Hogg, H. J. Holle, J. T. Hurst, E. B. Jamieson, Langworthy Laurie, R. G. Leach, E. A. Loch, S. L. M'Elderry, A. C. N. M'Hattie, A. J. Mackenzie, D. S. Macknight, H. J. M'Lean, J. M. A. M'Milan (M.A.), Angus M'Nab, G. W. P. Maitland, A. A. Martin, A. G. Martin, Henry Mason, F. C. Matthew (M.A.), M. M. Meikle, E. T. Melhuish, E. G. D. Menzies, S. H. Morris, J. A. S. Mouat, James Munro, H. C. Nixon, Norman Patterson, John Pender (with distinction), L. C. P. Ritchie, David Robertson, J. K. A. Robertson, G. A. P. Ross, R. A. Ross (with distinction), W. C. Ross, E. A. Savage, T. B. H. Scott, W. S. Scott, E. T. Selkirk, J. F. Selkirk, H. D. Shepherd, P. W. Shepherd, T. S. Shepherd, F. D. Simpson, G. W. Smith, J. A. Smith C. B. Snow, C. E Southon, G. B. A. Speirs, E. R. Sproull, C. S. Steavenson, T. G. Stewart, M. A. Swan, F. T. Thompson, J. H. Thornley, Alexander Trotter, Alexander Tweedie, C. S. Vartan, A. G. Watson, N. S. Wells, Angus Whyte, G. D. Whyte, F. M. Wigg, W. G. Williams, A. W. Wilson, M. R Wilson, T. J. G. Wilson, W. H. Winstanley, A. M. Wood (with distinction), C. G. Wotherspoon (M.A.), Frank Young (M.A.) (with distinction), and J. C. Zuidmeer.

Third Professional Examination (New Regulations).—Ivey Aird, John Anderson, Harvey Baird, W. J. Baird, C. A. J. A. Balck, W. J. Barclay (with distinction), E. F. Bashford, J. G. Bell, F. P. Bester, P. J. Bodington, G. A Brogden, W. J. D. Bromley, A. P. L. Brown, B. A. Brown, G. H. J. Brown, T. C. Caldwell, D. A. Callender, H. G. Carlisle, J. C. Carr, L. M. Chesney, B. J. Courtney, William Darling, H. B. Dodds, C. H. Durrant, David Ewart, William Ewart, W. R. Eyton-Williams, R. R. Fasson, Hugh Faulkner, David Fenton, David Ferrier, E. G. Ford, A. S. Frank, John Fullarton, J. J. Galbraith, H. A. H. Gilmer, J. H. Gordon, T. B. Gornall, F. J. Gray, A. H. Griffith, P. W. Hampton, F. J. Hathaway, G G. Hay, A. C. Heath, I. K. M. Hermon, H. T. Holland, A. M. Holmes, James Husband, J. G. Jack (with distinction), W. T James, R. F. Jardin, J. W. Kerr, D. B. King (M.A.), G. D. Laing, L. S. Lessing, Thomas Livingstone, E. A. Loch, J. L. Louis, James Luckhoff, B. G. Macdonald, J. M. Macdonald (M.A.), P. H. Macdonald, P. N. M. Macdonald, W. R. Macdonald, Harold Macfarlane, W. M. Mackay, Maxwell MacKelvie, H. M. Mackenzie, T. C. Mackenzie, George Mackie, R. C. M'Lachlan, P. A. Maclagan, L. Maclagan-Wedderburn, G. C. M'Leavy, R. A. Macneill, William Macniven, L. W. Macpherson, A G. Martin, Jas. Masson (M.A., B.Sc.), D. B. Merry, F. N. Menzies, G. H. Menzies (M.A.), James Miller (B.Sc.) (with distinction), J. G. Mitchell, R. M. Mitchell, J. R. Munro, W. A. Murray, A. W. Naukervis, T. P. Oates, James Orr, T. S. A. Orr, William Park, A. S Parker, A. S. M. Peebles, E. J. Peill, Arthur Preston (with distinction), R. M. Pringle, S. C. Pritchard, William Purves, H. G. P. Raeburn, F. G. Ralston, William Reid (M.A.), A. C. Renwick, Robert Ritchie, T. R. Robertson, Thomas Rogerson, E. M. Rowe, Sutherland Simpson (B.Sc.), C. E. Smith, A. K. Smith-Shand, V. E. Sorapure, Stephen Southall, W. J. Stuart (M.A.), W. W. Thom, G. N. W. Thomas, J. A. Thompson, R. G. Thomson, R. B. Turnbull, N. D. Walker, C. H. Watson, C. H. J. Watson (with distinction), Angus Whyte, A. S. Whytock, H. D. Wilson, A. H. Wood, and E. M. Young.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—**The following candidate has passed the examination for the diploma in State Medicine and Public Health :—**

H. Benson Goulding, F.R.C.S. Irel.

A CENTENARIAN.—**At the meeting of the Truro Rural District held on May 4th the medical officer of health (Dr. Bonar) reported that a woman named Mary Old of Kea had died at the age of 104 years.**

MORGAN DOCKRELL *v.* DOUGALL.—**On May 5th this case came on before Mr. Justice Kekewich in the Chancery Division of the High Court. Counsel for the plaintiff, a medical man, in opening said that this was an action brought to obtain a perpetual injunction against the defendant, who traded as the Sallyco Water Co., for using the plaintiff's name on a circular which stated that he was in the habit of ordering this water for "habitual use." To this the plaintiff objected, firstly, on account of the damage which would accrue and probably had occurred to his practice because of medical men believing he was guilty of unprofessional conduct in advertising by means of the "puff direct." Further, he objected because this water contained added drugs: colchicin, one-sixtieth of a grain, salicylic acid three grains to each half pint of aerated water. Colchicin being a scheduled poisonous alkaloid, this water might prove highly dangerous if used as an ordinary drinking-water like Apollinaris and not used as the plaintiff believed it ought to be—only under careful medical supervision. It was alleged that the defendant had given and broken undertakings not to publish any more circulars. At this juncture the learned judge intervened and said that as it was a case involving damage to reputation it ought to be submitted to a jury, and the case was then, with the permission of the Lord Chief Justice, transferred to the Queen's Bench Division.**

THE LONDON OPHTHALMIC HOSPITAL. — The festival dinner of the London Ophthalmic Hospital was held at the Grand Hotel on May 6th, when H.R.H. the Duke of Cambridge presided. In proposing the toast of the evening the chairman made a strong appeal for help and asked for a liberal response to his appeal. Sir John Lubbock, M.P., in responding, spoke of the value of the hospital in promoting the knowledge of ophthalmic science. Subscriptions to the amount of £1059 were announced by the secretary in the course of the evening.

FRENCH HOSPITAL AND DISPENSARY. — The thirteenth annual dinner in aid of the funds of this institution was held on May 7th at the Hotel Cecil. In the unavoidable absence of Baron de Courcel, the French Ambassador, the chair was taken by M. Leon Geoffray, the French Chargé d'Affaires, who was supported by the Lord Mayor and Sheriffs of London and many representatives of the *corps diplomatique et consulaire*. After the usual loyal toasts, including that of the President of the Republic, the chairman proposed the toast of the evening coupling with it the names of the Lord Mayor and Baron Whettnall. The Lord Mayor recalled the pleasure which his predecessors had always felt in assisting so deserving a charity and he took advantage of the opportunity to advise the management to take care that the funds were not expended on undeserving subjects, hospital abuse being a matter at present very much before the public. During the evening subscriptions amounting to upwards of £3000 were promised.

UNIVERSITY OF OXFORD.—That Oxford is well disposed towards its medical school is proved by the fact that in Convocation last Wednesday a decree was passed empowering the University to spend a sum of £7500 on the erection of a new laboratory and lecture theatre for the joint use of the Professors of Botany and Comparative Anatomy. As the Warden of All Souls stated when he introduced the decree in Congregation this step was necessary to provide accommodation for the increasing number of medical students. That the grant was passed without a dissentient voice speaks volumes, especially when it is remembered that the University chest is in a far from satisfactory condition. It is to be hoped that future grants will be as easily obtained, for the rooms at the disposal of the University lecturers on pathology and pharmacology are already insufficient to meet the requirements of these subjects or the number of students who desire instruction.—A public lecture on Pharmacology, its Aims and Methods, was delivered at Oxford by the newly appointed lecturer on materia medica and pharmacology, Dr. J. Smith-Jerome. In the course of an interesting address the lecturer remarked that the greater part of materia medica should be relegated to its natural habitat, the druggist's shop.

THE DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting of this society was held at 20, Hanover-square on April 26th, Dr. R. L. Bowles, in the unavoidable absence of Dr. J. F. Payne, being in the chair.—Dr. T. D. Savill brought a case for diagnosis—a Vesiculo-neurotic Eruption of probably Angio-neurotic Origin in a female aged fifty-two years. The eruption was practically localised on the lower third of left forearm back and front (mainly on the extensor surface) and on the back of the hand.—Mr. Hutchinson had seen the case and had been unable to give a name to it. After six weeks' treatment in a nursing home the patient had very much improved. A series of photographs of the case was shown.—Dr. Bowles, Mr. Pernet, and Dr. Travers-Smith joined in the discussion.—Mr. Pernet inquired whether the question of malingering had been gone into.—Dr. Savill also showed a case of Telangiectasis of the Face of recent origin in a man about thirty years of age.—Mr. W. T. Freeman showed a case of obstinate Lupus Erythematosus of the Face in a man aged twenty-eight years.—Dr. Savill suggested that it should be treated by the application of pure carbolic acid.—Mr. Pernet suggested soothing local applications.—Dr. Thompson showed, for Dr. Abraham, a man, about fifty years of age, whose body and limbs were almost smothered with eruption. Dr. Abraham called it lichen ruber acuminatus, as contrasted with pityriasis rubra pilaris. There was intense itching; it had existed for some weeks.—Dr. Bowles suggested oleum duline (a petroleum oil) locally and a skim milk diet.—Mr. Pernet said the eruption looked like an irritated acute lichen planus and suggested soothing local applications and rest in bed.

THE first annual dinner of the Chelsea Clinical Society was held at the Criterion Restaurant, Piccadilly, on Tuesday last.

ADVERTISING DENTISTS.—At the Cardiff County-court on May 5th, before Judge Owen, a female plaintiff sued a firm of dentists practising in Cardiff for £50 for personal damages. Counsel for the plaintiff showed that she had been attracted by advertisements stating that the defendants would supply a set of false teeth for 1 guinea, and she accordingly ordered a set at that price. After having twenty-two teeth cut or broken off she was informed that the guinea set would not do, but that she must have a 5-guinea set, and to this she agreed. The teeth, however, soon gave her trouble, and she went from time to time to the defendants, but they only made slight alterations. Eventually she was compelled to consult a medical practitioner, who treated her and advised her to see another dentist. This she did, and that gentleman found it necessary to extract twenty-two stumps, his fee amounting to £25 and the medical attendant's to £10. Counsel added that the plaintiff had been obliged to abandon a part of her claim in order to bring it within the jurisdiction of the court. The judge decided in favour of the plaintiff for £50 with costs.

DIPHTHERIA IN LONDON. — The deaths registered from diphtheria in London in the week ended April 30th were 39 in number and 4 in excess of the corrected decennial average for the corresponding week of the period 1888-97. The deaths in the three preceding weeks had been 29, 34, and 31 respectively and thus gave place to a distinct rise. Of the 39 deaths all were of persons aged under twenty years, 8 being of infants and other 25 of children under five years of age. The sanitary areas of Chelsea, St. Pancras, Islington, and Bethnal Green had each 4 deaths, and Hackney, Poplar, and Lambeth had each 3 deaths. There were 110 admissions to hospital in the week and 930 persons remained under isolation because of the disease at the close of the week—a fall from 1061 two months earlier. In the Outer Ring 14 deaths were registered from diphtheria, of which 6 occurred in Bexley sub-district and 4 in West Ham registration district. Last week the deaths from the disease registered in London declined to 27 and were 6 below the corrected decennial average for the corresponding week of the years 1888-97. All were of persons under twenty years of age, 23 being of children aged from one to five years. As many as 133 cases were admitted to hospital, 942 persons remaining under treatment last Saturday. In the Outer Ring 13 deaths were registered, of which 6 occurred in the West Ham registration district.

FREEMASONRY.—*Esculapius Lodge, No. 2410:* The last meeting of the session was held at the Café Royal, Regent-street, on the last Wednesday in April. Thomas Dutton, M.D.Durh., I.P.M. and secretary, presided in the unavoidable absence of the Master, E. H. Ezard, M.D., D.Sc. Edin. J. W. H. Eyre, M.D., M S. Durh., was admitted to the second degree, and W. C. C. Pakes, L.R.C.P.Lond., M.R.C.S.Eng., and O. Eaton, L.R.C.P.Lond., M.R.C.S. Eng., were initiated into Freemasonry. Surgeon-Lieutenant-Colonel H. W. Kiallmark, G.J.D., was elected Master for the ensuing year and G. Danford Thomas, M.D.Brux., coroner for Central London, treasurer. After the business of the Lodge was concluded the members dined together. Allusion was made to the honour bestowed on Bro. Kiallmark, who had just had the office of Grand Junior Deacon conferred upon him by the M.W.G.M., H.R.H. the Prince of Wales.—*Rihere Lodge, No. 2546:* A meeting of this Lodge was held at Frascati's Restaurant on Tuesday, May 10th, Bro. W. J. Walsham, W.M., being in the chair. Messrs. Briggs, Arthur Heath, and Stewart Mackintosh, junior, were initiated into Freemasonry. Bro. Launcelot Jowers was elected a joining member and Bros. Christopherson, Carnall, and Hoyland were admitted to the second degree by W. Bro. West. A sum of thirty guineas was voted from the Lodge funds to the centenary festival of the Royal Masonic Institute for Boys. W. Bro. T. G. A. Burns, was elected Worshipful Master for the ensuing year, and W. Bro. Godson, P.G.D., was elected treasurer.—*Universities Lodge, No. 2352:* The annual festival of this Lodge was held in the Masonic Hall, Durham, on April 28th, when Bro. George Hare Philipson, M.D., Professor of Medicine in the University of Durham, was installed as Worshipful Master of the Lodge.

UNIVERSITY OF WALES.—At the annual extra-collegiate meeting of the court of the University of Wales Dr. Isambard Owen, the retiring senior deputy chancellor, was re-elected and Lord Tredegar was elected junior deputy chancellor.

MEDICAL MAGISTRATES.—The Lord Chancellor, on the recommendation of the Lord-Lieutenant, has appointed Dr. George P. Bate of Hackney a Justice of the Peace for the County of London.—Mr. James Grant, M.B., C.M. Aberd., of Rhynie, and Mr. James Noble, M.D. Aberd., of Braemar, have been appointed Justices of the Peace for the County of Aberdeen.

THE LATE MR. GREIG SMITH.—A bronze bust of the late Mr. Greig Smith was unveiled in the Bristol Civic Museum on May 5th by the high sheriff (Mr. Richardson Cross, F.R.C.S. Eng.), who in a sympathetic speech alluded to the various services of the late distinguished surgeon. About £500 had been subscribed towards erecting a memorial to Mr. Greig Smith, £220 of which had been expended upon the bust, pedestal, and medallion and the remaining £280 had been handed to the Bristol Royal Infirmary towards the expenses of the new operating theatre.

UNIVERSITY OF CAMBRIDGE.—A Frank Smart Studentship in Botany, of the annual value of £100, will be vacant at Caius College in June. Candidates must have passed in honours the Natural Sciences Tripos, Part I., and after their B.A. degree undertake to pursue botanical research. Applications are to be addressed to the Master of the College.—Opportunities for research in zoology at Naples and Plymouth are offered at the university tables in these stations. Students who desire to be nominated should apply to Professor Newton, F.R.S., by June 1st.—Professor Kanthack will during the long vacation hold a number of classes in Pathology and Bacteriology; and Dr. Hill with Dr. Barclay-Smith in Practical Histology.

PRIZE ESSAY ON TUBERCULOUS CYSTITIS.—The Royal Academy of Medicine and Surgery, Barcelona, will award the "Dr. Garí Prize" next year for a paper on "A Clinical Study of Tuberculous Cystitis; its Clinical Tableau and Treatment." Three thousand francs will be given for the best essay and one thousand for the second best. The essays may be in Spanish, French or Italian, and must be sent to the Academy, Baños Nuevos, No. 9, Barcelona, before Sept. 30th, 1899. No essay may be in the author's handwriting or contain his name, but each must bear a motto and must be accompanied by a sealed envelope bearing the same motto and enclosing the name and address of the author. No prize will be awarded unless in the opinion of the judges sufficient merit is shown.

THE RE-NOTIFICATION OF INFECTIOUS DISEASES.—At Stonehouse (Gloucestershire) Police-court on April 28th Dr. E. A. Howsin of Stroud was summoned for failing to comply with the requirements of the Infectious Diseases Notification Act. Evidence showed that Dr. Howsin was called to Stonehouse to attend some boys suffering from scarlet fever and that he sent the usual notification to the medical officer of health for the Stroud rural district. Subsequently the cases were removed to Haresfield, which place is in another council's district, and Dr. Howsin omitted to re-notify. He explained that his breach of the law was through ignorance and that as soon as he became aware that re-notification was necessary he complied. The magistrates accepted this explanation and only fined the defendant 2*s.* 6*d.*, including costs. The landlady who received the cases into her house was also summoned for not notifying the same. The magistrates held that as she let lodgings she ought to be acquainted with the law and fined her 10*s.*, including costs.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Midwives Registration Bill.

THE Committee stage of the Irish Local Government Bill engaged the attention of the House of Commons on Wednesday, May 11th, to the exclusion of the Midwives Registration Bill. At the sittings on Monday and Tuesday Mr. Schwann presented a number of petitions in favour of the Bill, including petitions from the Obstetrical Society of London, the Midwives' Institute, and one "emanating," as Mr. Schwann said, "from a number of the leading members of the medical profession."

The Vaccination Bill.

At the same sitting as that on which the second reading of the Vaccination Bill was passed a number of Members handed in amendments in view of the committee stage. Mr. Channing proposes that an order directing a child to be vaccinated shall not be made on any person who makes a statutory declaration that he has a conscientious objection to the vaccination of his child and further that no vaccination officer shall initiate a prosecution under the Vaccination Acts if the board of guardians of the union shall have declined to authorise prosecution under the Acts. Mr. Labouchere's amendments are of a very sweeping character and practically involve repeal of all our vaccination laws. Mr. Hazell proposes that no order for the vaccination of a child "shall be made in any Poor-law union area wherever the guardians have, since the passing of this Act, passed a resolution by a majority of two-thirds of those present and voting to the effect that they are opposed to compulsory vaccination until such resolution shall have been rescinded by a similar resolution passed by a bare majority."

Corporal Punishment in Prisons.

The Bill of the Home Office for the reform of prison administration in England is in process of consideration by the Grand Committee of the House of Commons on Law. Several debates have taken place on the subject of corporal punishment and the outcome of them is that the Home Secretary has undertaken to draft a clause making this form of punishment permissible only in cases of mutiny and incitement to mutiny and of grave personal violence. Against the declared opinion of the Home Secretary the committee passed an amendment requiring that one of the Prison Commissioners shall be an expert in mental disease.

HOUSE OF LORDS.

THURSDAY, MAY 5TH.

Amendment of the Lunacy Laws.

The Lord Chancellor at this sitting of the House of Lords moved the second reading of the measure of the Government for the amendment of the Lunacy Laws. His Lordship explained that the Bill was substantially the Bill of last year and while wishing to meet every reasonable suggestion the Government proposed that the Bill should be passed into law before the end of the session. The main occasion for the introduction of the Bill was, he said, a feeling that the power to make urgency orders for the detention of persons supposed to be of unsound mind ought to be safeguarded. While this object was of great importance it was equally important to avoid doing anything which would interfere with the promptest treatment of proper cases. The urgency order was first devised to provide for cases where homicidal or suicidal mania occurred and where the delay occasioned by the ordinary procedure of applying to some judicial tribunal might be dangerous to the public and the patient. Although this modification of the law probably had not led to any real mischief in the way of persons not insane being shut up in asylums, yet in a large proportion of cases merely to save trouble urgency orders had been obtained when there was not the least pretence that there was any urgency at all. In one case an urgency order was made because the lady to whom it referred had peculiar views about the necessity of the marriage tie. In another case a lady was arrested under an urgency order while she was actually engaged in litigation and instructing her counsel. It was obvious that these orders were never intended for such cases and their employment in them constituted a gross abuse. It was impossible to avoid the use of these orders in the cases for which they were properly intended, but the Bill provided that any person who certified for one should be made responsible for any misstatement and should be compelled to give his reasons on the face of the certificate for the necessity of the order. Under these circumstances it would be difficult for the certifying person to avoid responsibility. The rest of the Bill dealt with points of detail which were entirely for committee, but, from the communications which had reached him, it was clear that discussion would be necessary. The question was where the line was to be drawn between local freedom of action and central control. The provision and administration of asylums were thought to be best undertaken by each county for itself; but a Central Lunacy Commission had been appointed to secure uniformity of principle in the treatment of lunatics. The best course was to trust to ability, discretion, and mutual confidence between the authorities concerned, to work out a system of this kind. But, unfortunately, cases had arisen occasionally showing that the intentions of the Acts relating to lunacy administration were not everywhere realised. There were two points illustrating this raised by Clauses 18 and 20. Under the existing law the plans for asylums had to be approved by the Secretary of State; but the Secretary of State had no power to intervene where the buildings, after completion, were used in a different way from that to which consent had been given. Cases had arisen where this had been done to an extent nullifying the Secretary of State's control. Clause 18 would make that control effective by requiring the arrangements of the asylum to remain in accordance with the approval given. He should hope to hear this clause more freely debated in Committee from a practical point of view and he should be glad to accept any amendments which would obviate ground for apprehending undue interference with local administration. The question of pensions for asylum officers was dealt with in Clause 20. When Parliament gave power to the counties to charge their funds with the expense of a pension system for asylum officers it never occurred to anyone that the power would not be universally and liberally used; but it had not, although it had been generally and satisfactorily acted upon. There was no class of public servants (as asylum officers were entitled to be

called) who deserved more consideration in this respect, both in their own interest and in that of the unfortunate persons of whom they had charge. To the principle of this clause he attached great importance, but he hoped that in Committee amendments would be moved to give the best possible shape to the proposal.—After a short debate the Bill was read a second time.

HOUSE OF COMMONS.

THURSDAY, MAY 5TH.

Enteric Fever among the Troops in India.

General Russell asked the Secretary of State for India whether the Government of India had arrived at any conclusion regarding the cause of the great increase in enteric fever among European troops in India; whether the investigations which it was promised should be made were concluded; and whether it was proposed to adopt any special measures to arrest the spread of this malady.—Lord George Hamilton replied: No definite conclusion has been arrived at as to the cause of the increase in enteric fever among British troops in India, and the investigations on this subject are still proceeding, selected medical officers having been specially detailed for this duty. Generally the measures taken to check the spread of the disease are the improvement of the water-supply, the provision of pure milk and butter, and improved sanitation of camp cantonments and barracks. One cantonment, Dragshais, where there have been serious outbreaks of enteric fever, has been completely evacuated for a year pending the installation of an improved water-supply and the disinfection of the barracks and their vicinity.

Vaccination Prosecutions.

Mr. Logan asked the President of the Local Government Board if it would be possible for a parent to be prosecuted three times on account of each unvaccinated child between the ages of twelve months and fourteen years, should the Vaccination Bill now before the House become law—viz., first, under Section 29 of 30 and 31 Vict. c. 84; secondly, by means of an application for a magisterial order under Section 31 of the same Act; and, thirdly, for disobedience of that order; and whether he had considered that the fines and costs in those three prosecutions might amount to the sum of £4 6s. 6d.—Mr. Chaplin replied: If the Vaccination Bill becomes law a parent could only be proceeded against twice for penalties in respect of the same child, once under Section 29 of the Act of 1867 and once under Section 31 of that Act; but before proceedings could be taken for a penalty under Section 31, a justice must, after summoning the parent to appear, direct the child to be vaccinated within a certain time. The maximum penalty in each of the two proceedings would be 2s. but a parent might be required to pay costs and the amount of such costs, I believe, varies in different districts.

First Aid in London.

Mr. Hubbard asked the Home Secretary whether any first aid was rendered to the wounded on the occasion of the disastrous collapse of a building in Orchard-street, Westminster, on the 21st ult. when a number of persons were injured, seven being killed, and whether any steps could be taken by the Government to develop an efficient ambulance service in London.—Sir M. White Ridley replied that the men injured by this accident were removed immediately to Westminster Hospital, only 350 yards distant. This was considered a better course than attempting to render first aid in the presence of a great and excited crowd. The five most seriously injured were, he was told, under treatment at the hospital within four minutes of the occurrence of the accident. Eight ambulances from different police stations and one horse ambulance arrived promptly on the scene, and of the 100 constables present 70 were competent to render first aid. He had every reason to think that the police ambulance arrangements were thoroughly efficient.

Royal Commission on the Disposal and Treatment of Sewage.

Mr. Chaplin made the following announcement on this subject—viz.: The Commissioners appointed are the Earl of Iddesleigh (chairman), Sir Richard Thorne Thorne, K.C.B., Professor Michael Foster, Professor William Ramsay, Major-General Constantine Phipps Carey, Dr. James Burn Russell, Colonel Thomas Walter Harding, Mr. Thomas William Killick, and Mr. Charles Philip Cotton. The Commissioners are appointed to inquire and report: first, what method or methods of treating and disposing of sewage (including any liquid from any factory or manufacturing process) may properly be adopted, consistently with due regard for the requirements of the existing law, for the protection of public health and for the economical and efficient discharge of the duties of local authorities; and if more than one method may be so adopted, by what rules, in relation to the nature or volume of sewage or the population to be served or other varying circumstances or requirements, should the particular method of treatment and disposal to be adopted be determined; and, secondly, to make any recommendations which may be deemed desirable with reference to the treatment and disposal of sewage.

The Plague in India.

Lord George Hamilton answering a question on this subject said: I have ascertained from the Viceroy that assurance has been given by the Bengal Government that wholesale quarantine against plague will not be enforced, but that arrangements will be made for inspecting travellers from infected localities, for segregating persons suspected of plague and for treating plague-stricken travellers. Members of families will not be separated when sent to segregation camps and the purdah system will be respected. Private plague hospitals and segregation camps are permitted. Inoculation is not enforced on any one, but arrangements are made for inoculating under Professor Haffkine's system persons who desire to be thus protected and special concessions have been made to encourage this form of inoculation.

FRIDAY, MAY 6TH.

Glycerinated Lymph.

Dr. Clark asked the President of the Local Government Board (1) whether his attention had been called to the report on sanitary measures in India for 1894-5 as to the use of lymph preserved with glycerine, in which it was stated that in the Madras Presidency preserved lymph was largely used, no fewer than 642,298 persons being vaccinated with lymph preserved with glycerine; that it was therefore no matter of surprise that of these only 89·2 per cent. proved successful cases of vaccination; and that the use of vaccine lymph mixed with glycerine was evidently not only an expensive procedure but disappointing in its results; (2) whether after a fair trial glycerinated lymph had been entirely discontinued in the Calcutta and Darjeeling depôts, the principal reason assigned by the sanitary commissioner of Bengal being that glycerine was a nutritive medium for the growth of putrefactive and other germs; (3) whether Sir George Buchanan also held a similar view regarding lymph preserved in glycerine; and (4) whether anything had been done to carry out the suggestion of the Royal Commission that there should be further investigation of this matter, and if so with what results.—Mr. Chaplin: In reply to the last paragraph of the question I stated in detail in the House nearly two months ago the steps which had been taken to carry out the recommendations of the Royal Commission with regard to the further investigation of this matter and also the results. Those results were eminently satisfactory and there is really nothing, I think, which I could add to what I said then. A report on the preparation and storage of glycerinated calf lymph with a full account of that investigation has also been laid upon the table. With regard to the memorandum referred to in the first paragraph of the question (relating to India in 1894-95) it does not appear how far the statements are based on reports which are described as being in many cases absolutely untrustworthy or under what conditions of laboratory precautions or otherwise the vaccine lymph at that date was mixed with glycerine. I do not understand whether the 89·2 per cent. successes referred to were insertion successes but even if they were they are in striking contrast with the successes reaching 97, 98, and 99 per cent. recorded in the report I have already referred to when the material was prepared under conditions of laboratory precautions such as are now being adopted. I am not aware that the use of glycerinated calf lymph has been discontinued on the ground stated in the districts in India which are mentioned and I am advised that it is not the fact that Sir George Buchanan held the view suggested in the question.

MONDAY, MAY 9TH.

Imported Milk.

Mr. Heywood Johnstone asked the President of the Local Government Board if his attention had been called to the recent report of Mr. Consul Gurney on the trade and agriculture of Cherbourg and district and, particularly to the paragraphs which refer to the large and increasing export of fresh milk to this country and to the statement that such milk was prepared for export by the admixture of some unknown antiseptic and that a certificate from a medical authority to the effect that the antiseptic was in itself innocuous would certainly be welcome and reassuring; and if he would take steps to obtain such a certificate and also a guarantee (as suggested by Mr. Consul Gurney) that no milk imported into this country has ever come from dairies where any of the inmates of the farm were suffering from infectious disease, and generally to insure that imported fresh milk was subject to the same sanitary safeguards and restrictions as milk produced in this country.—Mr. Chaplin replied: I am aware of the report referred to and the statements it contains. I entirely agree with my hon. friend in what I understand to be the object of his question, viz., that every precaution should be taken that milk imported into this country should be innocuous to public health. I have already taken steps for the chemical and bacteriological analysis of the milk imported from abroad, but with regard to the other guarantees that my hon. friend desires—viz., that the milk imported from France has not come from dairies where any of the inmates of the farm are suffering from infectious disease and is subject to the same sanitary safeguard and restrictions as milk produced in this country—that is a matter which at present is beyond my control. My hon. friend, however, is mistaken as to the large and increasing character of the trade from Cherbourg. The figures for the present year are as follows: January, 20,500 gallons; February, 28,500 gallons; March, 14,000 gallons; and April, 528 gallons.

Venereal Diseases in the Straits Settlements.

Mr. Duncombe asked the Secretary of State for the Colonies whether he had received a statement from the Straits Settlements Association showing that in the five years ending 1896 the ratio of venereal disease among the troops in the Tanglin district of Singapore was 434·17 per 1000, as against 144·81 per 1000 in the five years ending 1888, before the repeal of the contagious diseases ordinance, and containing statements by Brigade-Surgeon-Lieutenant-Colonel H. H. Stokes that of the sickness in his command 50 per cent. was venereal origin, and by Captain Bruce of H.M.S. *Orion*, which left Singapore in 1890, that more than half of the ship's company had been in hospital with venereal disease during the year; and what measures he proposed to take to prevent the continuance of a system under which such widespread disease involving such serious impairment of our military strength in the Straits Settlements was rendered possible.—Mr. Chamberlain said he had received this statement calling attention to a most serious state of affairs. As he had already informed the House he was in communication with the Governor of the Straits Settlements on the subject and the correspondence when completed would be laid upon the table.

The Vaccination Bill.

The debate on the second reading of the Vaccination Bill was resumed at this sitting and concluded and the measure was referred for further consideration to the Grand Committee on Law. Speeches were delivered by Mr. Hazell, Sir Charles Dalrymple, Mr. Channing, Mr. Labouchere, Mr. Ascroft, Dr. Farquharson, Dr. Clark, Mr. T. P. O'Connor, Mr. T. W. Russell, Mr. Whittaker, and others.—Dr. Farquharson suggested that the Government might have taken a somewhat stronger line, but at the same time he was prepared to support the Bill as a step in the right direction. The second reading of the Bill was carried by 237 to 23 votes.

TUESDAY, MAY 10TH.

Medals for Ambulance Work.

Mr. Cornwallis asked the Home Secretary whether he had come to a decision to recommend, in accordance with the terms of his speech at Blackpool, the bestowal of the Jubilee medal on those members of the Volunteer Medical Staff Corps (Maidstone Company) who were in previous possession of the certificate of the St. John Ambulance

Association and who did duty in London (treating 153 cases of injured people) on the occasion of the celebration of the sixtieth year of Her Majesty's reign.—Sir M. White Ridley replied: I find on inquiry that the case of these men is the same as that of the members of the Ambulance Brigade who have already received the medal, and am happy to be able to inform my hon. friend that I have given directions for the medal to be issued to them.

Smoke Nuisance at Westminster.

Mr. Labouchere asked the First Commissioner of Works whether he had noticed that a high chimney in close vicinity to the Palace of Westminster emits at all hours of the day clouds of black smoke and whether he would call the attention of the local authorities to this nuisance with a view to its discontinuance.—Mr. Akers Douglas replied that he had noticed the black smoke from this chimney and from many others elsewhere of late but the nuisance was probably due to the impracticability of getting Welsh steam coal during the strike. In any case, however, he had no authority in the matter and any representation on the subject should be addressed to the County Council.

Phosphorus Poisoning.

Mr. Pickersgill asked the Home Secretary whether, in accordance with his promise given on the 2nd inst., he had made further inquiry into the case of Cornelius Lean, lately employed at the match factory of Messrs. Bryant and May, who was poisoned by the yellow phosphorus used in the manufacture; whether he proposed to direct that proceedings should be taken against the occupier of the factory and the factory doctor respectively for neglecting to give the notices required by section 29 of the Factory Act, 1895; and whether it was intended to prosecute the factory doctor, under the Registration of Births and Deaths Act, upon a charge of wilfully misstating the cause of death upon the medical certificate.—Sir M. White Ridley said in reply: Yes; I have made further inquiries and a report of the result has been received this morning in the Home Office which requires very serious consideration. I have not yet had time to examine the report, but by Thursday I shall be in a position to say what steps I propose to take.

Midwives Registration Bill.

Mr. Hazell asked the First Lord of the Treasury whether he was aware that a large number of deaths of mothers and infants were annually proved at inquests to be the result of the employment of ignorant and untrained midwives and that this was the only civilised country in which such entirely untrained and unqualified action was permitted, and whether, under these circumstances, he would give facilities for the discussion on an early day of the Midwives' Registration Bill now awaiting its second reading.—Mr. Balfour replied that it was impossible to make an exception of this or any other private Members' Bill.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BELL, K. DE RISLEY, M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.

BENSON, P. L., M.D. Irel., D.P.H. Camb., has been re-appointed Medical Officer of Health by the Buckingham Rural District Council.

BOULTON, ARTHUR, M.R.C.S., L.R.C.P., D.P.H. Lond, has been appointed Medical Officer of Health by the Woodhall Spa Urban District Council.

BOWIE, J. C., M.B., C.M. Aberd., has been appointed Medical Officer of Public Health for the District including the Parishes of Sandsting Aithsting, Walls and Foula, and Sandness and Papa Stour in the County of Shetland.

BRISCOE, J. C., M.R.C.S., L.R.C.P., has been appointed Assistant House Physician to King's College Hospital.

CHENERY, A., M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.

DAVIES, A. O., L.R.C.P., L.R.C.S. Edin., M.R.C.S., has been re-appointed Medical Officer by the Machynlleth Urban Council.

DURRAN, D., M.B., C.M. Glasg., has been appointed Medical Officer of Health for the Burgh of Thurso, vice J. G. Smith, deceased. Also Medical Officer for the Combination Poorhouse, Halkirk, vice J. G. Smith, deceased.

FITZGERALD, JOHN J., M.D. Brux., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., L.A.H. Dub., has been appointed Fourth Assistant Medical Officer for the Cork District Lunatic Asylum.

FLUX, GEORGE, M.D. Brux., M.R.C.S., L.R.C.P., L.S.A., has been appointed Assistant Anæsthetist to the Dental Hospital of London.

GANGE, F. A., M.D. St. And., M.R.C.S., has been re-appointed Medical Officer of Health by the Faversham Rural District Council.

GARDNER, THOS. HUDSON, M.R.C.S., L.R.C.P., has been appointed House Physician to King's College Hospital.

HASSLACHER, F. J., M.R.C.S., L.R.C.P., has been appointed House Accoucheur to King's College Hospital.

HAWKESWORTH, THOS. A., M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.

HERBERT, B. H., M.R.C.S., has been re-appointed Medical Officer of Health by the Uttoxeter Urban District Council

HUNTER, DAVID, M.A., M.B., B.C. Cantab., L.S.A. Lond., has been appointed Assistant Medical Officer for the City Asylum, Newcastle-on-Tyne.

JAMES, PHILIP, F.R.C.S. Eng., has been appointed Surgeon to the Wellington Hospital, New Zealand.

JARVIS, W. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the St. George's No. 2 Sanitary District of the Parish of St. Giles, Camberwell.

JEFFARES, J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Kegworth Sanitary District of the Shardlow Union.

LEWIS, C. T., M.R.C.S., L.R.C.P., has been appointed Assistant House Accoucheur to King's College Hospital.

MARSH, J. H., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health by the Little Hulton Urban District Council.

MARTINEAU, A. J., L.R.C.P. Lond., M.R.C.S., has been appointed a House Surgeon for the Nottingham General Hospital, vice W. E. Smith, resigned.

MORRISON, A. T., M.B., B.Ch. Irel., has been re-appointed Medical Officer of Health by the Aylesbury Rural District Council.

PATTERSON, G. H., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. Lond., D.P.H Lond., has been appointed Medical Officer of Health for the Ulverston Union Combined Districts.

NELL, R. F., M.R.C.S., has been re-appointed Medical Officer of Health by the Penarth Urban District Council.

RANSOME, A. S., M.B., B.C., D.P.H. Camb., has been appointed Medical Officer of Health by the Southgate Urban District Council.

SIBBALD, I. G., M.B., C.M. Edin., has been appointed a House Surgeon for the Stirling Infirmary, vice W. A. Taylor, resigned.

STEPHENSON, WM., M.R.C.S., has been re-appointed Medical Officer of Health by the Beverley Rural District Council.

STRATTON, C. R., L.R.C.P., F.R.C.S. Edin., has been re-appointed Medical Officer of Health by the Wilton Urban District Council.

SUTTON, FREDERIC REGINALD, M.B., B.S. Durh., has been appointed a Resident Surgeon to the Birmingham General Dispensary.

WALLIS, P. E., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer of Health by the East Grinstead Urban Council.

WEST RIDING ASYLUM, Wadsley, near Sheffield.—Second Assistant Medical Officer. Salary £180, with board, &c., rising £10 annually to £230.

Births, Marriages, and Deaths.

BIRTHS.

CROOK.—On May 4th, at Dalby-square, Cliftonville, Margate, the wife of Herbert Evelyn Crook, M.D., B.S. Lond., F.R.C.S., of a son.

CROPPER.—On May 5th, at Mount Ballan, Chepstow, the wife of John Cropper, M.A., M.B., B.C. Cantab., of a son.

CUTTING.—On May 1st, at Chetwynd House, Stalham, the wife of Ernest B. Cutting, M.R.C.S., L.R.C.P., of a son.

DOUGLAS.—On April 4th, at Sanchez, Santo Domingo, the wife of Robert Douglas, M.B., C.M., of a son.

RODMAN.—On May 5th, at Heathcote, East Sheen, S.W., the wife of George Hook Rodman, M.D., of a son.

SANDALL.—On May 2nd, at Park-lane, Alford, Lincolnshire, the wife of T. Edward Sandall, B.A., M.B, B.C. Cantab., of a daughter.

SCOTT.—On May 7th, at Shooters-hill-road, Blackheath, the wife of Patrick Cumin Scott, M.B. Cantab., of a son.

SQUARE.—On May 9th, at Portland-square, Plymouth, the wife of J. Elliot Square, F.R.C.S., of a daughter.

USHER.—On May 1st, at Laurel Lodge, Dundrum, Co. Dublin, the wife of Isaac William Usher, L.R.C.S.I., of a daughter.

WINGRAVE.—On May 7th, at Allington House, St. Peter's-park, St. Albans, the wife of Wyatt Wingrave, M.R.C.S., of Devonshire-street, Portland-place, W., of twins (daughters).

MARRIAGES.

JOHNS—DICKINSON.—On April 26th, at Misson, by the Rev F. W. Keene, assisted by the Rev. H. McNaught, John Francis Johns, M.D., of 3, Lansdown-place, Cheltenham, to Lucie, third daughter of the late John Dickinson, Misson, Bawtry.

NORTON—NUNN.—On May 5th, at St. Mary's Church, Greenhithe, John Norton, M.D., D.P.H., of Queen Anne's-mansions, to Mabel, daughter of the late G. R. Nunn, of Lyndhurst, Hants.

RUDDUCK—TAYLOR.—On May 10th at St. Peter's, Bayswater, by Rev. E. W. Moore, assisted by the vicar of the parish, John Burton Rudduck, L.R.C.P., M.R.C.S., late of Assam, to Maude Mary Perston Taylor, late of Bethlehem and Morocco, eldest daughter of Robert Taylor, Solicitor, of 7, Bedford-row, W.C.

DEATHS.

KER.—On May 7th, at Hadley House, Cheltenham, Claudius Buchanan Ker, M.D. Edin., aged 77 years.

KINGLAKE.—On May 7th, at Wilton House, Taunton, Hamilton Kinglake, M.D.

MACKINTOSH.—On May 7th, at Chesterfield, Angus Mackintosh, M.D., Medical Officer of Health, Chesterfield Rural and Whittington, Dronfield and Clay-lane Urban Districts, aged 64 years.

PARTRIDGE.—On May 7th, at his residence, Thicket Lodge, Anerley, Deputy Surgeon-General Samuel Bowen Partridge, C.I.E., Q.H.S., Bengal Medical Service (retired), aged 69 years.

WALL.—On April 29th, after a long and painful illness, Alfred John Wall, M.D. Lond., F.R.C.S., Indian Medical Service (retired list), aged 50 years.

WILLIAMS.—On May 2nd, Arthur John Williams, M.R.C.S. Eng., L.S.A., of Upper Caterham, in his 39th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.).

WEDNESDAY (18th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2 30 P.M.).

Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.).

FRIDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (21st).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (16th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Annual Conversazione. Reception by the President. 8.45 P.M. Dr. F. Roberts: The Moscow Congress—a Holiday—with Comments on Suggested Topics.

SOCIETY OF ARTS.—8 P.M. Prof. C. Wilson: Electric Traction. (Cantor Lectures.)

TUESDAY (17th).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Annual General Meeting for the Election of Officers for the ensuing Session. Reports of the Morbid Growths Committee upon Specimens referred to it during the last six months. Dr. C. P. White and Dr. T. A. Bowes: Intestinal Obstruction due to Inflammation of the Great Omentum.—Dr. C. P. White: Sarcoma of the Kidney.—Mr. S. G. Shattock: Glanders Bacillus.—Dr. H. M. Fletcher: A Tumour of the Spinal Cord.—Dr. P. Weber: Microscopic Specimens illustrating an Apparent Thickening of the Subcutaneous Veins. Card Specimens:—Mr. H. J. Curtis: A large Lipoma of the Perineum.—Mr. S. G. Shattock: Experimental Infections in Animals.—Dr. C. P. White: Ununited Fracture of the Scapula.

WEDNESDAY (18th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—7.30 P.M. Exhibition of Microscopic Aquatic Life.

SOCIETY OF ARTS.—8 P.M. Mr. J. K. Starley: The Evolution of the Cycle.

FRIDAY (20th).—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (16th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 3 P.M., Dr. G. Stoker: Chronic Glandular Disease of the Nose and Naso-pharynx.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Mr. W. Wingrave: The Pathology and Histology of Lupus and Tubercle of the Upper Air Passages.

TUESDAY (17th).—LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abraham: Leprosy.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Sir W. R. Gowers: Lecture.

CITY ORTHOPÆDIC HOSPITAL.—5.30 P.M. Mr. J. J. Clarke: The Pathology and Treatment of Flat-Foot.

WEDNESDAY (18th).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: House Drainage.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Whitfield: Anæmia and Allied Conditions.

MASON UNIVERSITY COLLEGE (Birmingham).—4 P.M. Mr. J. W. Taylor: Extra-uterine Pregnancy. (Ingleby Lecture.)

NORTH-WEST LONDON CLINICAL SOCIETY (North-West London Hospital).—8.30 P.M. Demonstration of Clinical Cases.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Fowler: Clinical Varieties of Pulmonary Tuberculosis.

THURSDAY (19th).—LONDON POST-GRADUATE COURSE.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. Jonathan Hutchinson: Clinical Lecture.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Galloway: Demonstration of Skin Cases. (Post-graduate Class.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Batten: Cerebral Palsies in Children.

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Lantern Demonstration to Senior Students—Lung Disease.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.)—4 P.M. Dr. D. Grant: Chronic Catarrh of the Middle Ear.

FRIDAY (20th).—LONDON POST-GRADUATE COURSE.—King's College 3 to 5 P.M., Dr. Wilkinson: Anthrax and Malignant Œdema.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

THE DIFFERENCE BETWEEN "SKIMMED" AND "SEPARATED" MILK.

IN an appeal heard recently the decision of a magistrate that separated milk could not be regarded as skimmed milk was, we are glad to say, upheld. The vendor had supplied a tin of condensed milk upon the label on which were the words: "This tin contains skimmed milk with nothing added but the finest sugar." As a matter of fact the tin contained separated milk—that is, milk from which 97 per cent. of the original fat had been removed by a separator. Milk, on the other hand, when skimmed seldom yields more than 63 per cent. by the process. The decision was obviously logical and correct.

CLERICAL QUACKERY.

WE have frequently to point out in these columns that parochial clergy throw their ægis over quackery and even practise it themselves, regardless of the gravity of the possible consequences. A medical man sends us the following note which has been received by him and the original of which was, he says, in the handwriting of the clergyman of the parish, although it was signed by the patient's wife:—

C———.

DEAR SIR,—My husband is distracted with pain. Can you send anything to relieve him, or do you think it would be well to inject some morphia? If so, what quantity would you sanction? I understand Mr. R—— K—— could inject it if he had your sanction.

Yours respectfully,
J. H——.

P.S.—Please write a note.

Our correspondent informs us that Mr. K—— has on a previous occasion tried to introduce the services of a "cancer-curer" in this neighbourhood, so that it would seem that the reverend gentleman is rather bitten with the idea that he has a knowledge of medicine. We strongly advise him to leave off dabbling in what does not concern him before his willingness to administer deadly poisons to other laymen gets him into trouble. We do not say that his motives are other than kind, but his actions are very other than wise.

"SENSE OF FEELING IN A LOST LIMB."

THE following letter is taken from the *Literary Digest* published in New York:—

"The article, 'Sense of Feeling in a Lost Limb,' published in your issue of March 19th, interests me very much, and, thinking that a brief statement in regard to the same from a personal standpoint might interest your readers, I make it.

"My left leg was amputated at the middle third of the thigh over thirty-four years ago. The sensation of knee, foot, heel, hollow of foot, and toes being present is stronger than in the other limb. In fact, when at rest one is not conscious of any sensation in his limbs in a state of health; but in the stump the sensation is ever there, sometimes painfully so. This is no hallucination, but is due to anatomical and physiological reasons.

"Nerves of sensation pass out from the spinal column to every part of the surface of the body, each nerve having its own particular part to supply and each conveying to the nerve-centre knowledge that its terminal point is being irritated. Thus, a nerve terminating in the end of the big toe, no matter where it is irritated between the nerve-centre and the end of the toe, will say to the nerve-centre, 'The end of the big toe is touched or hurt.' When a leg is amputated all these nerves are gathered together and covered in by a healing of the stump, and it sometimes happens that they are firmly bound down by the cicatrix, and as it hardens, pressing upon them, sensations of pain occur, *not* at the end of the stump, but *at the point where each nerve terminated*. Just before storms, when the barometric pressure is light, the air within the tissues expands and presses on these nerve-ends, causing intense pain sometimes, and there is no relief but to reamputate the limb and see that the nerves are not caught in the cicatrix. It is generally the stump that perishe away and becomes small that gives the most annoyance.

My leg was amputated in such a position that when I stand it seems to be flexed with the foot behind me, and I have often tried to remove it from the way of persons passing, and have even tried to put it out to prevent the slamming of a door behind me, and much to my surprise the door did not stop. I have had many a fall in trying to walk, when springing up quickly I tried to put my foot to the floor. I have seen comrades whose legs were amputated below the knee, when on crutches, try to put the foot down and so come heavily on the end of the stump.

"As I grow older there is a sense of shortening in the leg, the foot seeming to come nearer the body. If I move the muscles of the stump, as in the effort to extend the knee, a sensation of great heat occurs at once in the stump, when it may be almost frozen with cold. Dry heat sometimes relieves pain in these stumps, but nothing will relieve permanently except an operation, as above stated. "H. A. DOBSON, M.D.

"Washington, D.C."

"SPIDERS, NOT COBWEBS."

AT a meeting of the Vestry of St. George-the-Martyr, Southwark, held on May 3rd, the medical officer of health, Dr. F. J. Waldo, reported as a result of an inspection made by him on the complaint of the new rector, the Rev. W. J. Somerville, that he was of opinion that "the close proximity of human remains (scattered in the form of bones and between 1000 and 2000 leaden coffins) in the crypt beneath the parish church of St. George's, where living beings are in the habit of congregating, is likely at any time to prove a danger to health." Dr. Waldo added that he had found extensive cracks in the ordinary brickwork of the walls and arches of the unventilated crypt, in which the air was musty, oppressive, and probably septic, and that Mr. Somerville's official request to inspect was the first and only one he had ever received. After a lengthened and heated debate (lasting upwards of two hours) the vestry resolved "to refer the matter back to the public health committee, with power to act and to take what steps they may deem necessary." Mr. Hilton, an old churchwarden and former chairman of the public health committee, urged as a proof

of the badness of the air and the need therefore of speed in action the fact that for some years past no spiders could be found in the belfry of the church tower. The atmosphere was so foul that they could not manage to live there. Mr. Redman, a prominent member of the health committee and a guardian, however, said that he had that day, in company with the two churchwardens, on inspecting the crypt been surprised by a living black cat which had jumped out of one of the gaping coffins. He had also found abundant evidence of cobwebs. Mr. Hilton retorted that he had said spiders, not cobwebs.

"GOUNA."

To the Editors of THE LANCET.

SIRS,—Gouna, as far as I know, is a drug little used in this country. It was brought to my notice some time ago by a gentleman on his return from the Cape of Good Hope and I have found it simply invaluable in obstinate ulcerations of mucous membrane on which the ordinary antiseptics, astringents, and other remedies had produced little or no effect.

Gouna is the Hottentot name for a species of mesembryanthemum and is said to be a domestic remedy used by the natives of the South African seaboard for a variety of ailments both internally and as a lotion or gargle. Internally it is used in the sore mouth of children during teething, in diphtheria, in chronic diarrhœa, scurvy, &c. Externally as a gargle in sore throat, white mouth, bleeding gums, and ulceration of the tongue and lips. I should be glad to hear the experience of others who may have used the drug in this country regarding its action and uses in their hands. I should add that I have satisfied myself that gouna is not a proprietary medicine.

I am, Sirs, yours faithfully,

JAMES ADAM, M.D. St. And.

West Malling, Kent, March 28th, 1898.

P.S.—Since writing the foregoing I have received the following further particulars from the Cape: "The 'gouna' is a very good remedy. The plant is the Mesembryanthemum edule (Linn). The prescription I make up is as follows: The expressed sap of the gouna leaves is evaporated to half the quantity; leave standing for ten days, boil again, and dissolve into it potass. chlor., add sp. vini rect. and filter. ℞ Succ. mesembryanthemi, ℥v.; potass. chlor., ʒiss.; sp. vini rect., ℥i.; M."

THE LATE MR. ARTHUR JEFFARES BARLOW: AN APPEAL.

AN earnest appeal is made by the following medical men to fellow practitioners and others on behalf of the young widow of Mr. Arthur Jeffares Barlow, who died suddenly on March 11th last at the early age of thirty-seven years. He was the eldest and only surviving son of the late Frederick Archer Barlow of 14, North Great George-street, Dublin, and will be remembered by many old friends and fellow students at Trinity College, Dublin. Unfortunately his position through ill health prevented his making any provision for his widow, who is without any means whatever and has no friends to assist her. She is in delicate health caused by long strain of nursing her husband and the shock of his sudden death. It is hoped that a generous response will be made to the appeal and that substantial aid may be given to such a sad and deserving case. Subscriptions will be received by Dr. J. W. Moore, 40, Fitzwilliam-square West, Dublin; Dr. John Barton, 26, Upper Merrion-street, Dublin; Dr. C. J. Clibborn, 76, Owen-terrace, University-street, Belfast; Dr. L. H. Ormsby, 92, Merrion-square West, Dublin; Dr. Henry, 2, Lewisham-park, Lewisham, London; Dr. A. Mateon, 619, Holloway-road, London. The following subscriptions have been received or promised:

	£	s.	d.		£	s.	d.
A Friend	5	0	0	Dr. J. W. Moore	1	1	0
Dr. John Barton	2	2	0	Sir W. H. Porter, Bart. ...	1	1	0
Dr. A. W. Baker	2	2	0	Dr. Clibborn	1	1	0
Mr. H. R. Swanzy	2	2	0	Dr. A. Mateon	1	1	0
Dr. J. Little	2	2	0	Dr. Henry	1	1	0

JOHN PAGE HENTSCH APPEAL.

To the Editors of THE LANCET.

SIRS,—The following further contributions have been received:—Mr. Sers, £1 1s.; Mr. J. W. Coles, 10s. 6d.; Mr. A. S. R. Wainwright, £10.

I am, Sirs, yours faithfully,

G. DAVID KNIGHT.

410, Brixton-road, S W.

Tibia.—The number of books on anatomy, physiology, medicine, and surgery is endless and there is not much difference between them. We offer our correspondent the following suggestions as to books for the Naval Medical Service examination:—Physiology: Foster's "Text-book," in four parts, or Waller's "Introduction to Human Physiology." Anatomy: Gray or Morris, and for surgical applied anatomy the excellent little book by Treves. Medicine: Pagge's "Text-book." Clifford Allbutt's "System" will be found very useful to consult upon particular subjects. Surgery: The "Systems" of Erichsen or Treves. Materia Medica: Lauder Brunton, "Text-book"; Mitchell Bruce, "Hand-book." French: This cannot be learned from a book. The best way to learn it is by the Gouin System and by reading French books of good literary style. Chemistry: Lewes, "Service Chemistry." Our correspondent is advised to refer to THE LANCET for Sept. 5th, 1896, where he will find fuller information than we have space for here.

Electro.—We have received no previous communication. There are certain conditions in which the process is useful, so that to practise it cannot be considered derogatory. We know of no pamphlet on the subject, but it is dealt with in all treatises on the use of electricity in medicine. A paper on the Electrolytic Administration of Drugs was read before the Harveian Society some years ago by the late Dr. Cagney and will be found in THE LANCET of Dec. 21st, 1889, p. 1285. For further references our correspondent is advised to consult Neale's "Digest."

Verax.—1. The Council have a perfect legal right to do as they have done, though it appears to us that their action is unnecessary. 2. We cannot express any opinion upon the views of the councillor mentioned without knowing the motives which impelled him to vote as he did. 3. Has the newly appointed medical attendant accepted the appointment?

Mr. Thomas Pyke.—We strongly protest against the introduction of alum into food, especially in a way unsuspected by the consumer. The new Food and Drugs Act adequately provides against the use of alum in baking powders but there is little prospect of the measure becoming law for some time yet.

Subscriber asks if any reader of THE LANCET can give him suggestions for a mechanical appliance "to prevent nocturnal masturbation," or can tell him of any preventive measures recommended in medical literature. The patient is mentally afflicted.

Mr. R. Martin.—The "worms" consist of little threads of dental pulp. Possibly the cleansing of the tooth and the removal of pulp by the process give relief. The idea of "worms" being ejected is mythical.

Cuba.—If our correspondent wants this information for medical purposes his medical adviser is the person to supply it. If he wants it for other purposes we are not the persons to supply it.

R. G.—It is not proposed to offer another Carmichael Prize. The present scheme has been found unworkable and application is being made to have it altered.

Mr. James Parker.—If the half of what you tell us were true you would be unable to write to us. You are recommended to consult your medical man.

Dr. Alfred Cox.—We shall notice our correspondent's communication next week.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

The Milroy Lectures

ON

THE NATURAL HISTORY OF VACCINIA.

Delivered before the Royal College of Physicians of London on May 3rd, 5th, and 10th, 1898,

BY S MONCKTON COPEMAN, M.A., M.D. CANTAB., M.R.C.P. LOND.,

MEDICAL INSPECTOR TO HER MAJESTY'S LOCAL GOVERNMENT BOARD; LECTURER ON PUBLIC HEALTH IN THE MEDICAL SCHOOL OF WESTMINSTER HOSPITAL.

LECTURE III.[1]

Delivered on May 10th.

ANIMAL VACCINATION.

MR. PRESIDENT, CENSORS, AND GENTLEMEN,—By the term "animal vaccination" as it is now applied is meant the employment for the vaccination of the human subject of the virus of cow-pox as propagated upon a succession of calves or heifers, the original virus having been derived from pocks upon the cow spontaneously affected with the natural disease. The late Dr. Ballard in his prize essay on Vaccination gives a most interesting and valuable historical account of the introduction of the practice. In this essay he states that the practice of animal vaccination appears to have originated with M. Negri in Naples, who was seemingly the first to propagate natural cow-pox by successive inoculations upon the heifer. Prior to his time, says Dr. Ballard, cows had been, in various places and by various persons, inoculated with vaccine virus derived from the human subject, the lymph obtained from pocks thus produced being used for human vaccinations. This practice has been termed "retro-vaccination." There appears to be no great difficulty or uncertainty attending retro-vaccination so long as animals sufficiently young are made its subjects and the human lymph is taken under circumstances favourable to its activity. The general result of reinoculation of it upon the human subject has been that the character and activity of the virus thus retransferred remained unaffected by its transmission through the system of the cow. This was the practice first pursued at Naples by Troja in 1805 shortly after the introduction of vaccination into Italy, and also pursued by his successor Galbiati. When, however, M. Negri, in 1842, succeeded to the practice on the death of Galbiati, he soon gave up retro-vaccination and began to propagate the virus by inoculation from one cow to another, that first propagated being of human origin. Subsequently, on the occasion of an outbreak of cow-pox in Calabria the use of this virus was abandoned and M. Negri propagated thenceforth that obtained from the natural cow-pox. It is said that on two occasions he thus availed himself of natural cow-pox matter obtained in Italy but that on a third occasion, in 1858, on which he renewed his supply, it was derived from London.

A good deal of doubt has been thrown upon the origin of this third renewal of virus and it has been questioned whether it was virus from natural cow-pox at all. However, it appears that it is this virus which M. Negri propagated subsequently to 1858. In 1864 M. Lanoix, a young French physician, visited Naples in order to study the practice of animal vaccination as pursued there. On his return he brought back with him to Paris a calf inoculated with the virus then in process of transmission by M. Negri, and in concert with M. Chambon he set up a private establishment for the propagation of the virus from calf to calf, and for the supply of animal vaccine in Paris. In his report on vaccination in France during 1864 M. Depaul, in the name of the Academie de Médecine, gave an account of the observations made in Paris on this subject, and in February, 1866, the French Government placed a sum of 6000 francs at the disposal of the Académie for the purpose of experiment in the matter. A Commission was appointed, the report of which was drawn up by M. Depaul. This report was favourable to the practice of animal vaccination. The Commission, however, were much divided in opinion, and the Académie did not then recommend that the practice should be adopted. At first the virus used by the Commission was that in use by MM. Lanoix and Chambon, and which they had previously obtained from Naples. But after four transmissions of this lymph had been made, a new source of virus from natural cow-pox was discovered at Beaugency (Loiret), and then the use of the Neapolitan strain was abandoned and this new and undoubted cow-pox virus was alone employed. MM. Lanoix and Chambon also adopted the use of this strain to the exclusion of that which they had before employed, and having in the autumn of the same year (1866) met with another case of natural cow-pox at St. Mandé, near Paris, they introduced this lymph also into their practice of animal vaccination. They saw no advantage in keeping these two lymphs distinct, and the strain which they have employed from 1866 onwards is a mixture of the two natural sources discovered at Beaugency and at St. Mandé.

Whatever the origin of the Neapolitan virus may have been therefore there can be no question that the inoculations made by the Commission (after the first four) and those afterwards made in Paris by MM. Lanoix and Chambon were transmissions of the virus of a cow-pox of spontaneous origin. From Paris the practice of animal vaccination extended in many directions. Thus in February, 1865, it was introduced into Brussels by Dr. Warlomont, whose first supply of lymph was obtained from M. Lanoix (Neapolitan source). At a later period he obtained from Paris virus in course of propagation from the Beaugency source, and still later he introduced a third source obtained in July, 1868, at Esneux (Liège). In September, 1866, at the request of the Minister of the Interior the Royal Academy of Belgium referred the whole question to a Commission consisting of MM. Bellefroid, Thieruesse, and Marinas, who reported favourably upon it. And, in consequence, in July, 1868, an "Institut Vaccinal de l'État" was established at Brussels, under the direction of Dr. Warlomont, for maintaining the practice of animal vaccination and distributing gratuitously lymph obtained from the animals or lymph taken from children who had been vaccinated direct from the animals, according to the preference of the vaccinators or other practitioners demanding it. The practice was introduced into Berlin by Dr. Pissin in June, 1865, and the establishment which he founded is still carried on as a private speculation. Animal vaccination appears to have been introduced into Vienna in a similar manner about the same time and many of the great capitals of Europe rapidly followed suit. Thus early in 1868 the Society for Promotion of Cow-pox Inoculation at Rotterdam determined to open a station for the practice of animal vaccination and they commenced operations in April of that year, distributing lymph throughout Holland and its colonies. A similar course was adopted in the following year by the corresponding society of Amsterdam.

Switzerland also owes the comparatively recent introduction of animal vaccination into that country to private enterprise, what is now known as the Institut Vaccinal Suisse having been founded in 1882 by M. Charles Haccius, the present Director of the establishment. Originally a private venture, the institute, which is situated at Lancy on the outskirts of Geneva, is now recognised by the various cantonal governments, M. Haccius, in consideration of an annual subvention, supplying to public vaccinators throughout Switzerland, free of cost, all the lymph required by them in the performance of their duties. This establishment I have recently (1897) had the opportunity of visiting in the course of a tour of inspection at the instance of the Government of certain of the chief calf vaccine establishments on the Continent of Europe. At Paris we found that, as is the case with the establishment of M. Haccius at Lancy, the Institut de Vaccine Animale is practically a private concern, although the municipality of the city of Paris contract with the Directors to carry out all such public vaccinations within their jurisdiction as may be necessary. This institution, which is now carried on by M. Chambon and Dr. St. Yves Ménard, was founded, as already mentioned, by M. Lanoix. Originally situated in the Rue Massillon, it was subsequently transferred to the Rue Ballu, where what was formerly a dwelling-house has been adapted to its present purpose.

In Germany all the establishments visited by Sir Richard Thorne and myself, at Berlin, Dresden, and Cologne respectively, are under Government control. Of these, that at

[1] This lecture was illustrated by means of a lantern demonstration. Lectures I. and II. were published in THE LANCET of May 7th and 14th, 1898, respectively.

Cologne is the most recent of its kind and its buildings with their fittings are of the most modern description. This institution, of which Dr. Vanselow is the Director, was erected in 1889 for the production of animal lymph to meet the needs of the Rhine province and Hohenzollern districts. The building adjoins the central meat market, a matter of convenience for the obtaining and subsequent disposal of calves. On the ground floor of the building are the collecting room, calf stable, slaughter room, director's and clerks' rooms, corridors, and offices; while on the first floor is a bacteriological laboratory, fitted up with all needful apparatus, which is reached from the collecting room by an iron spiral staircase. At Brussels the propagation, storage, and distribution of calf lymph is carried out at the École Véterinaire under the supervision of Professor Dégive, the Director of the establishment. The accommodation provided in the present building is regarded as very insufficient for the purpose and accordingly, as Professor Dégive informed us, a new vaccinal institute is about to be erected in the construction of which all modern scientific requirements will be amply provided for. The private establishment originally founded by Dr. Warlomont and which is now carried on by his son-in-law, an officer in the Belgian Army, we had not the opportunity of visiting.

Although the practice of animal vaccination is now practically universal throughout Europe, in England up to the present time it has been employed to a very limited extent. At the Government Animal Vaccine Establishment at Lamb's Conduit-street, which was founded in 1881 as the result of investigations by the late Sir George (then Dr.) Buchanan and Dr. Cory, direct vaccinations of children from calf to arm have been carried out from that date onwards to the present time. From the calves vaccinated at Lamb's Conduit-street lymph has also been supplied to public vaccinators in quantity sufficient to enable them to start their periodical vaccinations, and provision has also been made for supplying a comparatively small amount of lymph to private practitioners in addition. The lymph thus sent out has for the most part been preserved by drying on ivory "points," although a certain proportion has been stored in the liquid form in capillary glass tubes. Until quite recently, however, all public vaccinations in this country, with the few exceptions just mentioned, were required to be performed by direct transmission of the virus from arm-to-arm, stational attendance at fixed periods having been arranged for in order to render feasible such method of operating, weekly attendance having been provided in large towns, while quarterly or even half-yearly periods suffice for the required purpose in scattered country districts. As the result, however, of the findings of the Royal Commission on Vaccination legislative measures are about to be introduced by which arm-to-arm vaccination will be entirely superseded, in public work at any rate, by animal vaccination; and the adoption of the use of preserved glycerinated calf lymph having been determined on, the necessity for stational attendance will disappear except in so far as may appear desirable for purposes of control or in order to provide facilities for teaching. The principal grounds on which the practice of animal vaccination has been advocated are, firstly, the opinion, widely though not universally held, that the results of vaccination from arm to arm are not such as they used to be in the earlier years of the practice of vaccination; in fact, that by repeated human transmission the virus has become weakened and that the pocks produced by the introduction of lymph which has passed through a large number of human beings are not so fine or so perfect as those which result from the use of animal lymph. Jenner himself, indeed, appears to have been under the apprehension that lymph-stocks would be liable to degenerate as the result of long-continued transmission through the human subject. In the present state of our knowledge, however, such enfeeblement of the specific virus can hardly be regarded as probable, except under such conditions as may be obviated by reasonable skill and care on the part of the operator. Jenner early discovered that vaccine lymph only exhibited its full degree of activity when taken at the stage of maturation of the vesicle and before its contents became at all purulent. If this precaution be observed, together with strict cleanliness in removal and insertion of the lymph, experience has shown that no appreciable degeneration can be demonstrated. Secondly, the opinion that certain other human diseases may be propagated together with vaccinia when vaccinations are performed from arm to arm. Galbiati, who was one of the first, if not the first, to vaccinate with bovine lymph, adduced this belief as his reason for practising vaccination from the cow, arguing that on vaccinating the cow from the human subject vaccinia alone would be communicated to her, any other morbid germs which might be introduced along with it remaining without effect. He considered apparently that in practising retro-vaccination according to the method which he devised he, as it were, filtered human vaccine material from any possible contamination. As the result of all the evidence brought before them during the lengthy period of seven years the English Royal Commission on Vaccination have reported that the risks incurred from arm-to-arm vaccination "are undoubtedly real and not inconsiderable in gross amount," although "when considered in relation to the extent of vaccination work done they are insignificant." And they add that "there is reason further to believe that they are diminishing under the better precautions of the present day and with the addition of the further precautions which experience suggests will do so still more in the future." It is, indeed, acknowledged on all hands that cases of syphilis can be and unfortunately have been occasionally conveyed from one human being to another as the direct result of vaccination; and although the number of cases which can be authenticated are extraordinarily small in number there is advantage in the adoption of a method which while equally efficacious entirely obviates the possibility of so lamentable an occurrence. Erysipelas and tuberculosis are also two of the not inconsiderable number of diseases with the spread of which vaccination has been credited. No doubt the greater proportion of cases of erysipelas following on the process are of what has been termed "late" origin. These are due to infection of the vaccination wound at or about the time when it has been customary to open the vesicle. The general use of animal vaccination by obviating the necessity for opening the vesicle may be expected to be followed by a diminution of cases originating in the manner suggested, though accidental injury to the arm or the use of improper dressings will doubtless prevent the complete disappearance of erysipelas or other septic diseases. Invaccinated erysipelas, however, we may anticipate will shortly become in great measure, at any rate, a thing of the past; and fortunately the possibility even of the invaccination of tubercle may be eliminated as the result of the treatment of calf vaccine with glycerine after a method which I first advocated some years ago and which has now been officially adopted by the Government.

GLYCERINATED LYMPH.

In a paper presented to the International Congress of Hygiene held in London in 1891, and subsequently published in the Transactions of that Congress, I called attention to a special method for the bacteriological purification and preservation of vaccine lymph. This method consisted in the intimate admixture of a given amount of lymph, or rather vesicle pulp, with a sterilised 50 per cent. solution of chemically pure glycerine in distilled water and in subsequent storage of the resultant emulsion in sealed capillary tubes for several weeks. For some years antecedent to 1891 I had been engaged in investigating the nature and mode of action of the specific virus contained in vaccine lymph, chiefly from the bacteriological point of view. Early in the course of my experiments it struck me that the exuberant growth commonly manifested by what were so evidently "extraneous" organisms might be very possibly interfering with, if not superseding, the more important and essential organism which I was seeking. I therefore turned my attention to the discovery, if possible, of some means of so treating vaccine lymph as to inhibit the multiplication in it of all "extraneous" organisms and eventually to destroy them altogether, without at the same time injuring its potency for vaccination. These bacteria evidently find in the lymph, especially when removed from the body, a suitable medium for their subsequent multiplication, while at the same time it would appear that growth and multiplication of them has the result of gradually inhibiting the specific effect proper to the vaccine virus itself. Upon all grounds, then, the obvious indication for my guidance was not only to prevent such multiplication of "extraneous" organisms subsequent to storage in the usual manner, but if possible to remove them altogether as soon as the lymph was taken from the living subject, without injury to the actual contagium of vaccinia. Without detailing the various experiments adopted with this object in view it is necessary here to state

briefly the lines on which the work was carried out. In the first place, trial was made of the method of exposure of lymph for definite periods to a temperature considerably above blood-heat, which had in the hands of Kitasato met with conspicuous success in the isolation of the bacillus of tetanus. Proceeding in this manner, and in every experiment observing the precaution of making control cultures, I presently arrived at a temperature, exposure to which is apparently incompatible with the continued existence of those micro-organisms which can ordinarily be grown when vaccine lymph is inoculated into nutrient jelly. The temperature in question ranged between 38° C. and 42° C., but the method did not in practice prove advantageous. Thus if plate cultures were made of lymph after exposure for an hour at the lower register a few points of growth occasionally after the lapse of a day or so made their appearance; and, on the other hand, the higher temperature, though it inhibited all extraneous microbes, appeared sometimes to exert an injurious effect on the lymph as far as regards the normal vesiculation which should result from its inoculation in the living animal. Some method of readier application and requiring less delicate manipulation was therefore obviously desirable. This I at length found in the addition to the lymph, or rather to the vesicular pulp, obtained from a vaccinated calf, of a sterilised 50 per cent. solution of chemically pure glycerine in distilled water prior to storage of the mixture in capillary tubes which had themselves been previously sterilised by heat.

Admixture of glycerine and vaccine lymph is, of course, no new device. Indeed, my attention has recently been directed to a letter by the late Mr. R. Cheyne which appeared in the *Medical Times* as long ago as March, 1850, in which he advocates the superiority of lymph which has been kept in the fluid state by addition of "the least portion" of glycerine over that which has been dried on points. As Mr. Cheyne's work appears to have been overlooked until quite recently, it may be of interest to set out in his own words his mode of procedure. "My method," he says, "is to take all the lymph I can get from the eighth-day vesicle on a glass stopper (elongated in a narrow tongue-shaped form for about an inch below the neck of the small bottle into which it fits) and, having accumulated it on both surfaces of the stopper near its end, I mix it well with the point of the probe, with the glycerine held by the latter. Then after the stopper is put into the bottle (which is always to be kept standing up) the lymph, then assisted by gravity, will collect itself into a distinct drop on each surface of the stopper, to be ready for use, as I know by experience, during a very long period and in any number of cases that would not exhaust the stock." In a further letter Mr. Cheyne acknowledges his indebtedness to the late Mr. Startin's advocacy of the therapeutic applications of glycerine, by which he learnt of the suitability of this substance for the object he had in view and sets out practically in the wording of Mr. Startin's paper the distinctive properties of this substance, among others, that of its being an antiseptic. He goes on to say: "I mixed glycerine with vaccine lymph in the way detailed ..... with the satisfactory result, better than any theory, of discovering that in addition to its known property of preventing fermentation and mouldiness in vegetable substances it had also that of keeping vaccine lymph, an animal product, undecomposed in a fluid state for months." Three years later (in 1853) Mr. Cheyne showed to the Presidents of the Royal Colleges of Physicians and Surgeons a child whom he had successfully vaccinated with lymph which he had previously kept for six months after treatment with glycerine.

It was left for Müller of Berlin in 1869 to demonstrate the further point that the quantity of matter available could be increased by the addition of glycerine without injuriously affecting the potency of the mixture. He showed that vaccine lymph might be diluted with three times its bulk of glycerine and still retain its properties unimpaired—a fact which has been taken advantage of at many of the continental vaccine stations and by more than one purveyor of lymph. Curschmann writing on the subject of small-pox in Ziemssen's Encyclopædia refers to this method as follows: "Müller has the great credit of having discovered the fact that by mixing vaccine matter with glycerine in certain proportions the activity of the former is not diminished, so that we have here a means of *increasing the volume of the lymph* when the quantity is small or when there is an unusual demand for it. ..... The lymph and glycerine mixture *appears to keep as well as the unmixed lymph.*"[2] But from this statement it is quite obvious that the sole object of employing glycerine in the manner described was to increase the amount of material available for vaccination. Also with this end in view glycerine was used by Dr. Stephen Mackenzie at the London Hospital in the epidemic of 1870–71, the mixture of lymph and glycerine being made up immediately before it was required for a large series of revaccinations. Similar means for increasing their amount of available lymph have been frequently employed by public vaccinators (among the earliest my present colleague, Dr. Bruce Low) and others in times of stress. In 1882 Dr. Warlomont patented in England a method of admixture of glycerine with vaccine lymph, but no mention of the use of glycerine in this connexion was made in the advertisements of his agents until within the last few months. Until recently, moreover, there would seem to have existed no appreciation of the inhibitory action exerted by glycerine in bringing about bacteriological purification of the lymph, when the mixture is stored for some time prior to use under conditions preventing access of air and light. When, however, a glycerine emulsion is properly prepared after the method I have advocated it is found that the growth of extraneous aerobic bacteria is at once greatly inhibited, while after a longer or shorter period they are practically all killed out. This effect is best demonstrated by making a series of plate cultivations from tubes of glycerinated lymph at gradually increasing intervals of time, a control plate being poured in each instance from a specimen of the lymph material prior to the admixture of the glycerine. These observations of mine, since their publication in 1891, have received ample corroboration from a number of observers in various parts of the world as follows:

In 1892 a paper dealing with this question was published by MM. Chambon and St. Yves Ménard in which they relate their experience of the use of glycerinated calf-lymph when kept for a considerable period in capillary glass tubes (previously sterilised) closed by the blow-pipe. Not only were the results they obtained with originally active lymph highly satisfactory, but lymph which in its fresh state had given mediocre results produced, after 15 days' admixture with glycerine, a passable vesicle, and after 40, 50, or 60 days a typical one. The improvement in the activity of such lymph seemed to them to be due to the gradual extinction of extraneous microbes under the combined influence of glycerine and time. Professor Straus, who made plate cultures with their glycerinated lymph, found that when fresh it gave rise to numerous colonies of various microbes, especially staphylococcus pyogenes aureus and staphylococcus albus, but that when it had been stored from 50 to 60 days, plate cultures therefrom remained absolutely sterile as regards these extraneous microbes. Samples tested at intervals between these two extremes presented fewer and fewer microbes as they became older. These experiments were repeated many times and invariably with similar results. This evidence, so entirely corroborative of my own work, is the more important as it appears certain from a perusal of their original paper that the authors were ignorant that similar results had been previously arrived at and that these had been published nearly twelve months before the appearance of their article.

The value of glycerine in this connexion is also strongly advocated by Leoni in a paper read before the Medical Congress held at Rome in April, 1894, and afterwards published in the *Révue d'Hygiène*. He finds that vaccine lymph as freshly collected is apt to contain large numbers of micro-organisms, some of which, he says, are capable of exerting pathogenic properties when inoculated into the system along with the true vaccine virus. And he states that these microbes disappear completely from, or that at least their number is vastly decreased in, vaccine which having been prepared with glycerine is afterwards preserved for a period of from one to four months before use. His conclusions may perhaps be best given in his own words: "Le vaccin récemment recueilli est un vaccin contaminé." "Les agents de la contamination s'épuisent dans le vaccin conservé pendant quelque temps dans la glycérine." "Le vaccin conservé dans la glycérine pendant 1 à 4 mois après la récolte, représente le type du vaccin *pur* d'une *virulence uniquement spécifique.*" "C'est de cette qualité de vaccin que l'hygiéniste doit aujourd'hui tenir compte dans la prophylaxie de la variole." Dr. Klein also bears witness to the power

[2] The words italicised do not so appear in the original.

exerted by glycerine in freeing vaccine lymph from bacteria. In speaking of the organism specific to vaccinia as being probably a spore-bearing bacillus he says: "..... It is established that the active principle of vaccine is preserved in glycerine, although, as is also known, pure glycerine acting for long times is a germicide for cocci and sporeless bacilli."

In 1896 a Commission under the presidency of Dr. Schmidtmann—and including Dr. Koch, Dr. Pfeiffer, and Dr. Frosch, together with the directors of the vaccine institutes of Berlin, Cologne, and Stettin—was appointed by the German Government to inquire and report as to the best methods for the collection, preservation, storage, distribution, and use of vaccine lymph. In their report, which has been recently published, the Commissioners arrive at the conclusion among others that fresh lymph contains numerous microbes, the number of which, on the addition of glycerine, diminishes as the age of the mixture increases. To determine to what extent glycerine is efficacious in destroying the vitality of various definitely pathogenic microbes numerous streptococci and diphtheria bacilli were mixed with specimens of lymph. As a result the streptococci were killed in eleven days and the diphtheria bacilli in twenty days. Attempts by these experimenters, as also by Kitasato in Japan, to make other chemical agents serve for rendering vaccine lymph free from bacteria led to no results of value, as although the lymph could thus be rendered free from extraneous bacteria it was found to be inefficacious as vaccine. Their next procedure was to determine the amount of glycerine that could be added to lymph so as to exert a powerful action in purifying it from extraneous microbes without in any way interfering with its specific action when employed for the vaccination of children or calves, and they came to the conclusion that the mixture of glycerine with distilled water could be employed to the extent of from 15 to 20 times the weight of vesicle pulp collected without interfering with the value of the material for the purpose of vaccination.

By consent, therefore, of numerous observers fully qualified to judge of the matter we have in glycerinated calf lymph properly prepared a vaccine material which, while even more efficient as vaccine than the original lymph, can be produced practically free from the extraneous organisms which at one time or another have been isolated from fresh or stored lymph by the method of plate-cultivation. Of not least importance is the fact that, as shown by Dr. Blaxall and myself, vaccine lymph may by this method of preparation with glycerine be rendered free also from pathogenic bacteria, such as those of tubercle and erysipelas, even when these have previously been added in considerable quantity for experimental purposes. The fact that the growth of the tubercle bacillus is well known to be encouraged in a nutritive medium containing about 5 per cent. of glycerine in no way detracts from the value of this substance when used in a strength of from 40 per cent. to 50 per cent. as a means of obtaining lymph free from pathogenic organisms. That particular drugs when introduced in small quantities into the human economy seemingly stimulate and encourage certain of its functions, whereas when introduced in large quantity they discourage or even annul them, is a fact familiar to every practitioner, and it is also well known to bacteriologists that micro-organisms are profoundly affected by variations in one or another direction of the amount of one and the same chemical constituent of the particular medium in which they are placed. The question of quality of vaccine lymph naturally engaged the attention of the English Royal Commission on Vaccination at a time when they were taking the evidence of witnesses and among the recommendations contained in their final report is one to the effect that no persons should be required to submit to vaccination by means of any other lymph than that derived from the calf. The reason for this recommendation appears to be avoidance of even remote risk of inoculation, in the process of vaccination, of infections other than cow-pox — such, for instance, as those of syphilis and leprosy (Section 433)—as also the desirability of minimising the opportunity for infection by erysipelas by obviating the necessity for opening vaccine vesicles involved in arm-to-arm vaccination (Section 447). The succeeding section of the report which deals specially with the subject now being discussed may be set out in full. It is as follows:—

"448. We think that safety would be increased by preserving the lymph in tubes instead of on 'dry points.' There is some difference of opinion on this matter among those with whose opinions we have been furnished. On the whole, however, we think the weight of experience as well as reason is in the direction we have indicated. In connexion with this subject our attention has been drawn to the experiments recently made by Dr. Copeman as to the effect of the storage of vaccine lymph in glycerine. The conclusions at which he arrives are that the addition of glycerine, whilst it leaves the efficacy of the lymph undiminished, or even increases it, tends to destroy other organisms. If it be the fact that the efficacy of the lymph remains unimpaired its storage in glycerine would largely diminish the difficulties connected with the use of calf lymph which are inseparable from calf to arm vaccination. The investigation has not reached a point at which it is possible to pronounce with certainty whether the anticipated results would be obtained. And it was at one time suggested that the introduction of glycerine was likely to be mischievous. The question is one a further investigation of which is obviously desirable. If lymph is to be preserved in glycerine due care would be requisite to ensure its purity and the absence of contamination in its introduction. We think that, whether mixed with glycerine or not, each tube should contain only sufficient lymph for the vaccination of one person.

In this Section (448) of the Royal Commissioners' report a sentence occurs to which some special reference is desirable. This is as follows: "And it was at one time suggested that the introduction of glycerine was likely to be mischievous." The reference made is to an outbreak of disease having the clinical characters of impetigo, which occurred in the summer of 1885 in villages situated on the island of Rügen in the Baltic, after the vaccination of 79 children in the latter part of June of that year. This outbreak forms the subject of a paper by the late Sir George Buchanan in the Transactions of the Epidemiological Society for 1885–86. He states that for the vaccination of these 79 children only two tubes of lymph (of human origin) were available and consequently their contents were further mixed with glycerine (glycerinum purissimum) before use. Thymol to the extent of one-third had also been mixed with the lymph previously to its having been sent out from the Government establishment at Stettin. Sir George Buchanan states that the principal misgivings of the Commission appointed to inquire into the outbreak had concern with the glycerine, but adds that several points in the circumstantial evidence, however, suggest that the Stettin mixture *before glycerine had been added* may have been responsible for some irritation. He further says, however: "I do not know of any experience in England of inoculation with thymol or thymol and glycerine, but I have heard of dilutions of lymph with glycerine always from people complaining of the lymph." In giving evidence before the Royal Commission on Vaccination in 1893 I was asked whether this statement did not condemn my suggested use of glycerine in connexion with lymph supplies. I pointed out, however, that in the first place dilution of lymph with an indefinite quantity of "glycerine" of unknown composition just before employing the mixture for vaccination, was a very different matter from storing lymph with chemically pure glycerine in definite amount and of definite strength, the whole being protected from light and air for a length of time before use and that in addition what at the time of the outbreak in question may have been termed glycerinum purissimum would in all probability at the present day be considered by no means deserving of that term. This latter statement I made on the authority of Messrs. Price, the chief manufacturers of glycerine in this country, whose manager at the request of the directors was good enough to put at my disposal his extensive practical knowledge of the details and the literature of this subject. The information thus obtained has been published in the appendix to the last volume of evidence recently issued by the Royal Commission on Vaccination. The glycerine which has been employed in my investigations is that manufactured in this country by Messrs. Price, but in Germany, where this method of purification and preservation is now carried out in all the Government establishments for the supply of vaccine lymph, a glycerine made by Sarg of Vienna is used. This is said by Dr. Schultz, the director of the Berlin establishment, to be of a less "drying" nature than English glycerine. In order to obtain an authoritative opinion as to the degree of chemical purity obtained in the manufacture of glycerine at the present time and also an accurate estimate of the difference, if any, in the nature of the English and Austrian brands, I requested Dr. Wilson Hake to analyse samples of glycerine manufactured by Messrs. Price and by Sarg respectively, and also samples of a new English brand which had just been placed on the market by Messrs. Lever Bros. The result of the chemical examination of these samples, which Dr. Hake was kind enough to make for me, proves incontestibly that all three samples exhibit a high degree of purity, most

markedly so in the case of Messrs. Price's manufacture. In all there is complete absence of metallic contamination of any kind, while the amount of organic impurity is insignificant. The main difference observed is the slightly greater degree of concentration obtained in the English products as opposed to that of Austrian manufacture.

In accordance with the suggestion contained in Section 448 of the Report of the Royal Commission the Local Government Board instructed me to make arrangements with Dr. Blaxall, the lecturer on Bacteriology at Westminster Hospital, and now Bacteriologist to the Government vaccine laboratories, to carry out a further series of experiments on the lines indicated by me in the evidence which had been tendered to the Commission, with the object of elucidating more fully the exact value of my glycerine method for the purification and preservation of vaccine lymph. The results of this series of experiments are set out in the report of the medical officer to the Local Government Board for the year 1895–96, published in the autumn of 1897. Although devoting our attention mainly to the results which ensued on the employment of glycerine, it was thought desirable that investigation should be made concurrently as to the possible value for the preservation and purification of vaccine material, of lanoline and vaseline, substances which within quite recent years have been introduced by two officers of the Indian Medical Service, Surgeon-Lieutenant-Colonel King and Surgeon-Major Bamber respectively, as being superior in their opinion to glycerine as agencies for the preservation of vaccine.[3] Neither of these observers, however, has as yet brought forward any bacteriological evidence as to a possible germicidal action of the substance they advocate, as will be seen on reference to their original papers. And Dr. Blaxall has shown that from this point of view at any rate neither lanoline nor vaseline can be regarded as possessing any value whatever. Indeed, it would appear that the extraneous organisms originally present in the lymph with which these substances are admixed, so far from exhibiting as time goes on any diminution in numbers, tend on the contrary to become largely increased as shown by the test of plate-cultivation. Lanoline and vaseline are thought by their advocates to possess superiority over glycerine mainly for the following reason. These officers note that glycerine emulsion tends to become mouldy after a short period, whereas this they do not find to be the case when either lanoline or vaseline is employed. That glycerinated lymph should have suffered deterioration in the way they indicate suggests either that it was not properly prepared or that it was left exposed to the air. That the occurrence of a similar accident is not an impossibility with lanoline and vaseline preparations has been demonstrated by Dr. Blaxall's recent experience of their use.

The advantages of glycerinated calf lymph may be set out as follows: 1. By employing the method of glycerination of lymph-pulp great increase in quantity can be obtained without any consequent deterioration in quality, the percentage insertion success following on its use being equal to that obtained with perfectly active fresh lymph. 2. Glycerinated lymph does not dry up rapidly as does unglycerinated lymph, thus simplifying the process of vaccination. 3. Glycerinated lymph does not coagulate, so that it never becomes necessary to discard a tube on this account. 4. Glycerinated lymph can be produced absolutely free from the various streptococci and staphylococci which are usually to be found in untreated calf lymph and which are considered by Crookshank and others as liable to occasion suppuration. 5. In like manner the streptococcus of erysipelas, in the event of its having been originally present in the lymph material, is rapidly killed out by the germicidal action of the glycerine. 6. The tubercle bacillus is effectually destroyed even when large quantities of virulent cultures have been purposely added to the lymph. 7. The possibility of inoculation of syphilis is eliminated, as the calf is not subject to this disease. 8. The necessity for collecting children together, with the attendant risk of spread of infectious diseases, or of transporting a calf from place to place, is obviated, while the danger of "late" erysipelas in the child is minimised by reason of there being no necessity to open the mature vesicles for the purpose of obtaining lymph. 9. The bacteriological purity and clinical activity of large quantities of the lymph can be readily tested prior to distribution. 10. By reason of the possibility of keeping large stocks of glycerinated lymph on hand for considerable periods of time without appreciable deterioration, any sudden demand such as is likely to arise on outbreak of epidemic small-pox can be promptly met. 11. The expense of producing glycerinated lymph is proportionally small, since the amount obtainable from each calf is enormously increased.

[3] The use of vaseline as an excipient for vaccine material had apparently been advocated by Professor Layet of Lyons some years previously to Surgeon-Major Bamber's first communication on the subject.

THE PREPARATION OF GLYCERINATED CALF LYMPH.

The method best adapted for the production of glycerinated calf lymph which shall be free from all extraneous organisms, of perfect efficacy, and yet affording material for the vaccination of many more children than the original unglycerinated calf lymph, is briefly as follows.

The preparation of the calf.—A calf of suitable age, about from three to six months old, should be kept in quarantine for a week, after which, if found to be quite healthy, it may be removed to the vaccination station. It is there placed on a tilting table and the lower part of the abdomen, reaching as far forward as the umbilicus, having been shaved is thoroughly washed with a solution of carbolic acid and then rinsed with sterile water and dried with soft sterilised towels.

Inoculation of the calf.—With a sterilised sharp scalpel, incisions parallel to the long axis of the body are made on this clean-shaved area. The depth of the incision should be such as to pass through the epidermis and to open the rete Malpighii, if possible without drawing blood. As these incisions are made, glycerinated calf lymph, which by examination has been proved to be free from extraneous organisms, is run into them by means of a sterilised blunt instrument and the point of the scalpel is also from time to time dipped into the vaccine emulsion.

Collection from the calf.—After 5 days, or 120 hours, the vaccinated surface of the calf is first thoroughly washed with warm water and soap, rubbed over it by the clean hand of the operator, and finally the whole area is carefully cleansed with sterile water. The remaining moisture is then removed by sterilised sheets of blotting-paper. The vaccinated incisions will now appear as lines of continuous vesicles raised above the surface, each line separated from its neighbour by about ¼ in. of clear skin. Any crusts which appear in the vesicular lines are picked off with a blunt sterilised instrument. The vesicles and their contents are then removed by means of a sterilised Volkmann's spoon and transferred to a sterilised bottle of known weight. By going over the lines only once with the spoon it is quite easy to remove the whole of the pulp without any admixture of blood. The abraded surface is carefully washed and may be dusted over with fine oatmeal or starch and boracic powder. Subsequently the calf is transferred to the slaughter-house and the carcass is examined by the veterinary surgeon, who forwards a certificate of its condition. Should this not be satisfactory the vaccine pulp obtained from the animal is destroyed.

Preparation and glycerination of the lymph-pulp.—The bottle containing the vaccine pulp is taken to the laboratory and the exact weight of the material ascertained. A calf vaccinated in this way will yield from 18 to 24 grammes, or even more, of lymph-pulp. This material is then thoroughly rubbed up in a sterilised mortar or in a mechanical triturating machine. When it has been brought to a fine state of division it is mixed with six times its weight of a sterilised solution of 50 per cent. chemically pure glycerine in distilled water. The resulting emulsion is then transferred to small test tubes, which are then aseptically sealed and should be stored in a cool place protected from light. When required for distribution it is drawn up into sterilised capillary tubes which are subsequently sealed in the flame of a spirit lamp.

Bacteriological examination of the lymph emulsion.—As soon as the vesicular pulp is thoroughly emulsified with the glycerine solution agar-agar plates are established from it and after suitable incubation for seven days the colonies that have developed on the plates are counted and examined (see Figs. 1 to 5). Week by week this process is repeated and invariably the number of colonies diminishes with the age of the emulsion, until at the end of the fourth week (see Fig. 6) after the collection and glycerination of the lymph material the agar-agar plates inoculated at that time show no development of colonies. The lymph is then subjected to further culture experiments and if these results of freedom from extraneous organisms are confirmed the emulsion is ready for distribution. The elimination of the extraneous organisms in our experiments has occurred with

marked regularity at the end of the fourth week. The only exception to this rule arises when the lymph originally contained a considerable number of spores or bacilli of the hay bacillus or bacillus mesentericus. These organisms are very resistent to the action of glycerine, but if the precautions detailed are carried out in the treatment of the calf their presence may generally be excluded.

FIG. 1.

Photograph of agar plate incubated for seven days subsequently to inoculation with *one loopful* of rubbed-up vaccine material *prior* to its admixture with glycerine.

Duration of activity of glycerinated calf lymph.—This varies in all probability with atmospheric conditions, with the fineness of division of the vesicle pulp, and, above all, with the condition of the calf itself. Some calves yield an excellent lymph, others a poor lymph, and the problem is to determine the value of the lymph yielded

FIG. 2.

Photograph of agar plate incubated for seven days subsequently to inoculation with *five loopfuls* of the same material *immediately after* glycerination. The number of colonies on these two plates (Figs. 1 and 2) will be observed to correspond closely.

by any given calf. A lymph which was collected and glycerinated on July 13th, 1897, has since been used at intervals of from 24 weeks to 32 weeks after glycerination for the vaccination of children. During this period 61 children have been vaccinated with this lymph in 5 places each, with a mean insertion success of 98 per cent.[4] Thus by the methods described glycerinated calf lymph can be prepared which becomes freed from extraneous organisms is available for a large number of vaccinations, at least 2000 from an average calf, and retains full activity for ten months and will, under favourable circumstances, continue to do so in all probability for still longer periods if

FIG. 3

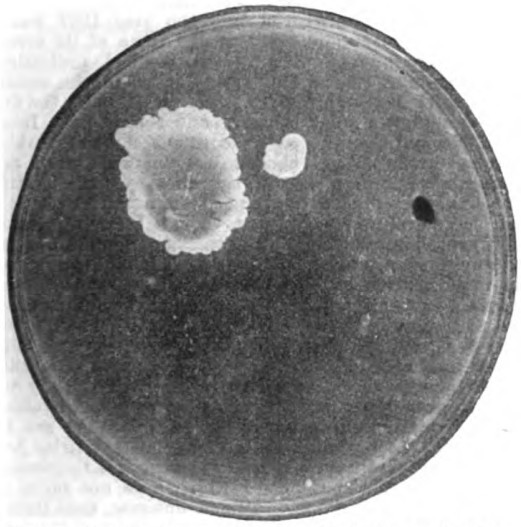
necessary. In practice, however, there will, of course, be no reason for keeping lymph for such a period.

From the description which I have given it will, I think, be obvious that the preparation and testing of glycerinated calf lymph, properly so-called, is a matter requiring considerable skill and care. Sir Richard Thorne insists strongly

FIG. 4.



Photograph of similar agar plate inoculated *a fortnight after* glycerination. A further decrease in the number of colonies is now conspicuous.

on this fact in his introduction to our joint report recently presented to Government on the administration of certain of the chief continental vaccine establishments. "In every

[4] This same sample of lymph (now forty-two weeks old) has given in Dr. Cory's hands during the past week an insertion success (based on 50 insertions) of 100 per cent.

instance," he says, "we found that the work of collecting preparing, and storing the glycerinated lymph was carried out with the greatest care; a condition of scientific cleanliness was especially aimed at, and a laboratory, fitted with bacteriological and other scientific apparatus, always formed an essential part of the vaccine institution. The extent to which the desired end of freedom from extraneous impurity was

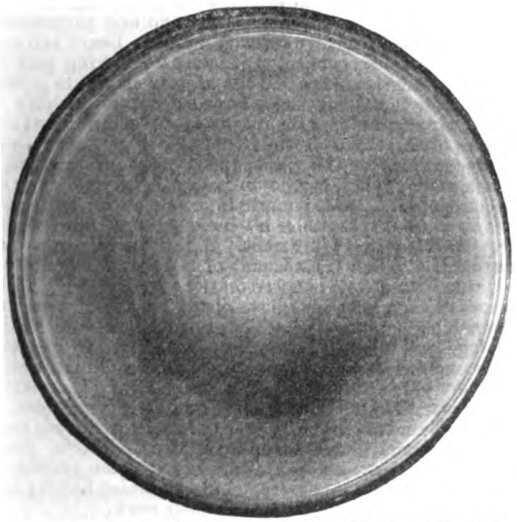


FIG. 5.

Photograph of similar agar plate inoculated *three weeks after* glycerination. The decrease in the number of colonies is still more marked than in the former plates.

attained depended largely on whether a first attempt to adapt an existing calf station or similar establishment to its new purposes had been maintained, or whether it had been abandoned in favour of an institution constructed especially for the purposes of that which is in the main scientific laboratory work. Several of the stations which we visited are already under condemnation because of the difficulty

FIG. 6.

Photograph of similar agar plate inoculated *four weeks after* glycerination. No growth whatever has occurred.

of ensuring that freedom from micro-organisms which should be aimed at during the preparation of the lymph-supply; the Cologne station is one of the newest and may well serve in its main features as a type of that which should be aimed at. The condition of scientific cleanliness to which I have referred extended to such matters as the following: (*a*) the construction and administration of the stabling for the calves; (*b*) the means of washing or bathing calves before their vaccination; (*c*) the construction, cleansing, &c., of the operating rooms; (*d*) the cleansing of the vaccinated surface of the calf with germicidal preparations and sterilised cloths before collection of the lymph; (*e*) the use of clean sterilised outer garments by all officials concerned in the processes carried out; (*f*) the sterilisation of all instruments, &c., employed; and (*g*) the admixture of the lymph material or pulp with glycerine, its preparation and storage under conditions of laboratory freedom from extraneous organisms.

"With a view of meeting all possible criticism as to the chance of conveying tuberculosis together with calf lymph we found that, notwithstanding the well-known rarity of that disease in calves, together with the now recognised germicidal effect on the tubercle bacillus when deliberately added to calf lymph prepared with an aqueous solution of glycerine as described, it was the practice not to issue any lymph until a report had been received from a veterinary surgeon—after slaughter of the animal—of the freedom of the calf in question from tuberculosis or other disease. In brief, the lymph used is that of healthy calves only.

FIG. 7.

Photograph of child (eighth day) vaccinated with glycerinated calf lymph, which, as shown in Fig. 6, had been found, when tested by the method of plate cultivation, to be free from extraneous micro-organisms.

"The information which we obtained in the course of our visits does not profess to be complete. Much remains to be ascertained by careful scientific research in order to learn what are the precise conditions under which glycerinated calf lymph can be prepared and stored, so as to secure, to the utmost, freedom from extraneous and, especially, from pathogenic micro-organisms, whilst at the same time retaining to the utmost the undiminished protective value of the lymph material against small-pox. In every country visited further research is being made in this direction and in Germany a special commission of medical and bacteriological experts has been appointed by the Government in order to study and report upon the subject. But the information which is now available in this country and that which during the course of our visits abroad was placed at our disposal with a readiness and a courtesy which calls for an expression of the fullest acknowledgment suffices to enable me to submit the following conclusions:—

"1. It is desirable that vaccination, both primary and secondary, carried out under the auspices of the Government, should be performed exclusively with vaccine lymph derived from the calf.

"2. There will probably be advantage in retaining, for a time at least, the system of calf-to-arm vaccination at the Board's Animal Vaccine Station for such parents and others as may request it and for the purposes of comparing its results with those following the use of calf lymph preserved in one or another way.

"3. The distribution of calf vaccine from the National Vaccine Establishment should be limited to glycerinated or similar preparations of lymph or pulp material in air-tight tubes or other glass receptacle.

"4. To give effect to the above it will be requisite that the Board's Animal Vaccine Station should be reorganised both as regards construction and administration. Notably will it be requisite that it should include a properly equipped laboratory under the direct supervision of a bacteriological expert."

These recommendations are now in process of adoption by the Government and already suitable laboratories have been secured which are to be placed in the charge of Dr. Blaxall. I trust, therefore, that we shall shortly be in a position to supply bacteriologically pure and fully active calf vaccine lymph in any quantity that may be found desirable.

An Oration

ON

THE MOSCOW CONGRESS—A HOLIDAY; WITH COMMENTS ON SUGGESTED TOPICS.

Delivered before the Medical Society of London on May 16th, 1898,

BY FREDERICK T. ROBERTS, M.D., F.R.C.P. LOND.,

PROFESSOR OF MEDICINE AT UNIVERSITY COLLEGE; PHYSICIAN TO, AND PROFESSOR OF CLINICAL MEDICINE AT, UNIVERSITY COLLEGE HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—You, Sir, with the other members of the Council of the Medical Society of London have again, from purely friendly motives, lured me from the obscurity and retirement for which I instinctively crave and for which nature intended me and have thrust me into a conspicuous and much-coveted position. I should indeed be wanting in appreciation of such kindness, and even in mere courtesy, if I did not express at the outset my feeling of deep gratitude for the honour thus conferred upon me, especially as it is wholly undeserved. I am, however, none the less conscious of my unfitness for the task and of my deficiency in the qualifications necessary to command the attention and interest of such an audience as is gathered together on an occasion like this, most of whom are, I have no doubt, impatient and eager to take part in the more attractive social functions of a conversazione, to enjoy a chat with friends whom probably they seldom meet except at these times, and to indulge in the delights of the "fragrant weed." And yet, Sir, you have now actually designated me an "orator!" Fortunately for my peace of mind this word has nowadays a very wide and indefinite signification and by no means implies the possession of the faculties or powers which were originally associated with the expression and which in ordinary language it is supposed to suggest.

With the view of getting a hint as to a suitable topic for this address I asked our always obliging and courteous registrar—Mr. Hall—whether he could furnish me with a list of the subjects dealt with in previous orations. There was no such record, but he at once took the trouble to prepare one and as the result I have here a list of the orators since 1774 and of the topics on which they discoursed, so far as they are known at present. I have thus at least the satisfaction of being responsible indirectly for calling into existence a record which, while of great interest in itself, will be of much value for future reference. I found, however, that it did not help me materially, except by showing that the subjects presented great variety and that I was at liberty to be guided entirely by my own inclination in selecting one. Of course favourite themes were, in addition to matters relating to the Society itself, the grandeur of our profession as well as its defects, its internal and external relations, how to promote its progress, and the remarkable advances, real or supposed, made from time to time in the various branches of medicine and surgery. These are always tempting and attractive topics, which open up channels for any amount of talk, but for various reasons I personally rather shrink from them, and at any rate they are sufficiently discussed at the present day not to call for any special reference to either of them on this occasion.

I need scarcely remind you that the year 1897 was a memorable one in several respects and some of its events have had important relations to the medical profession. Amongst those of special interest to us were the annual meeting of the British Medical Association, held for the first time in one of our great colonies, and the Twelfth International Medical Congress at Moscow. For reasons which I need not enter upon I chose to attend the latter; and "The Moscow Congress" seemed such an easy way of getting out of any difficulty in deciding upon a subject that I determined to inflict it upon you, though I have no doubt most of you, either from personal experience or from reading the accounts in the medical and lay press, know as much about it as you desire. I must therefore appeal to your kind indulgence on this ground amongst others, that in days to come the mere record in the Transactions of the Medical Society of London of the fact that the International Medical Congress was held in Moscow in 1897 may prove interesting to future generations, and especially that this society was represented as a delegate by its esteemed and distinguished president, Dr. Sansom. I regret to say that I am not the first in the field, for others in this and other countries have given addresses on their Russian experiences and impressions in connexion with the Congress, which does not make my task any the easier or lighter. I hope, however, that there is still something left for me to speak about, and there are aspects of the subject which, so far as I am aware, have not yet been dealt with.

It must seem at first sight highly incongruous and absurd to associate, as I have done, the idea of "a holiday" with the Moscow Congress. To think of going from one large city to another in the height of the hot season, attending crowded meetings as well as fatiguing evening social gatherings and entertainments, most of them continued into the "early hours," and calling such an experience a holiday! Moreover, judging from remarks I have heard, it seems to be a deep-rooted notion amongst the laity, as well as amongst many medical men who do not honour congresses with their presence, that those who do attend such gatherings are consumed with an ardent desire for scientific and professional progress and consequently devote themselves heart and soul to the active work connected therewith, taking part in various discussions, reading and listening to elaborate papers, absorbing and imparting fresh knowledge, and helping to bring into practical utility the results of all sorts of novel and marvellous discoveries. I think, Mr. President, you will agree with me that on the whole this is a delusion, though there are no doubt a few who take things very seriously on these occasions. I may remark in passing that individual notions as to what constitutes a "holiday" and how it may be best spent are very different. A few years ago a very interesting and delightful account of a "Doctor's Holiday" formed the topic of one of these orations by Dr. Ord. There was an air of calm and restfulness about his experiences that made them highly attractive. Others must be always killing something, but in saying this I do not mean to cast any reflection upon members of our profession. Others, again, make a very toilsome business of a holiday, being incessantly "on the move," taking "record" walks or bicycle rides, or climbing some mountain peak, and the more dangerous their exploits the keener the pleasure they derive therefrom. Some stay at home perpetually, being so devoted to the practice of their profession that this is to them a constant holiday and they are miserable when away from their work.

Speaking personally I am glad to say that I can thoroughly enjoy different kinds of holidays, provided I am not expected to put forth too much energy and needlessly risk my life and limbs. From more than one point of view the visit to Moscow might fairly come under the category, for at any rate it afforded a rest and change from the ordinary routine of London life, professional and social; while, altogether apart from the Congress itself, one could not but feel deeply interested in the novel sights and experiences associated with a most remarkable country and city not previously

visited and in observing and gaining some acquaintance with the Russian people, their conditions, habits, and mode of life. But in the title of my address I have coupled the idea of a holiday with the Moscow Congress for a special reason. I wish it to be clearly understood that in relation to this event I held an entirely unofficial, independent, and individual position. I was not even a "delegate" from any society, association, corporate body, or university, but a mere "outsider," an "item," an "unit" in that vast gathering, occupying a very "back seat" and decorated with the simplest badge which the Congress could furnish. Do not imagine for a moment that I am complaining of this. I rejoiced in my liberty and took full advantage of it. I felt that I could spend my time exactly as I liked, so long as I conducted myself in accordance with Russian regulations and ideas, disregard of which might lead to unpleasant consequences. Further, I was calm in the happy consciousness that unless I chose to do so I was not called upon to take any active part in the work of the Congress, nor had I looming before me the prospect of having to give an account of my doings or to prepare any official report. And now, Mr. President and Gentlemen, I am ashamed to confess that I did nothing of which there will be any record in the proceedings of the Moscow Congress. The Transactions of this society will bear testimony to the general fact that I never read papers anywhere if I can possibly avoid doing so, and I must say that I do not regard it as the height of bliss to be obliged to listen to them, especially when they are practically inaudible and delivered in, to me, an unintelligible language. As to taking part in a discussion I shudder at the mere thought. I am fully aware that in these days such conduct is very foolish from several important points of view and I by no means commend it for imitation. On the contrary, I take this opportunity of strongly advising the "rising generations" of the medical profession to bring themselves to the front as much as possible if they wish to succeed, and to assert themselves, not only at home but abroad, and especially when they attend foreign congresses. I cannot answer for members of other professions, for men engaged in commerce, for explorers of new countries and so-called "pioneers of civilisation," for politicians or statesmen; but as regards the members of the medical faculty in this country I have a strong impression that as a class we are not so forward or "pushful" as we might be and in this respect are far behind certain other nations. Consequently their representatives are always to the fore at these gatherings and only too ready and eager to assume prominent positions. At the Moscow Congress a few of our representatives were invited to occupy more or less conspicuous positions, or to read communications on special subjects. We were all particularly pleased to see Sir William Mac Cormac presiding at the last of the general meetings and he conducted the proceedings in his customary dignified and genial manner. Dr. Lauder Brunton upheld the honour and prestige of his country by delivering one of the addresses at the first great meeting. Our distinguished Fellow, Dr. Pavy, read a communication on Diabetes by special invitation. Others were elected vice-presidents or presidents of Sections and occupied the chair at some of these gatherings, amongst them the President of this society. A few of their own free will sacrificed their comfort to their sense of duty by reading papers or joining in discussions. On the whole, however, our countrymen kept very much in the background and the record of actual work done at the Moscow Congress will not contain so many names of our well-known leading men as might be wished. And now, Mr. President and Gentlemen, I have further to confess, as bearing out my idea of a holiday, that I did not even attend the meetings of the Sections as diligently or regularly as I might or ought to have done. In duty bound I entered my name for one of them—namely, that of the "Maladies Internes"—and did spend a little time there at intervals. Moreover, I looked in at other sections in a casual way, more from curiosity than anything else, and was sometimes much entertained, if not edified or instructed.

My remarks up to this point will have prepared you for the announcement that I am not in a position to give such an account of the scientific and practical outcome of the proceedings of the Moscow Congress as you might reasonably expect. For this perhaps you will be grateful, for a disquisition on this line is apt to be very tedious and trying for an audience. But while I did not actively engage in the work of the Congress I desire at once to remove any impression that I looked upon the occasion as a mere pastime or that I intend to deal with my subject in a wholly frivolous and irresponsible fashion. In relation to the gathering itself one could not help feeling a real interest in the proceedings, observing and taking note of events and circumstances connected therewith, reflecting upon the work done and the subjects dealt with, and endeavouring to realise and estimate the present position of our profession, as well as the comprehensive or cosmopolitan tendencies of modern thought and practice in relation to the "science and art of medicine," using the expression in its widest sense. Moreover, a medical congress suggests, either directly or indirectly, many questions of the deepest interest and importance to us as a profession and I regard my independent and unofficial position at Moscow as affording me full liberty to refer to any matters of current interest which fairly come within the range of my theme and to express my personal opinions and feelings in relation thereto.

Before dealing briefly with some of the more prominent events immediately relating to the Moscow Congress I must just allude to a difficulty which pertains more or less to all international congresses, but which in this case assumed unusual proportions, and that is as regards the matter of languages. Personally, I must regretfully admit that I am very deficient in knowledge of foreign tongues and much of my remissness in listening to papers and discussions was, as I have already hinted, due to this cause. I have an impression that not a few of my fellow countrymen were not much better off than myself, though some, on the other hand, excited our envy by being able to discourse fluently in public in French or German. But I was particularly struck, not only with the advantage of a thorough knowledge of these and other of the more familiar modern languages, but also with the importance of cultivating the faculty of acquiring languages. I desire to enforce this point emphatically upon my younger hearers. At the present day you have very great advantages over your predecessors and are expected to have a tolerable acquaintance, at any rate, with French and German, especially if you aim at taking a high position in your profession. This is necessary even for literary purposes, but I would remind you that to carry on a conversation in these languages and to follow with comfort the business of a foreign congress are very different matters from merely knowing just enough to enable you to read books and articles on professional subjects. I met some American friends at Moscow, who, being adepts at learning languages, from prolonged training, and possessing much determination, arrived there with a very fair knowledge of Russian, which served them, and their companions sometimes, myself amongst the number, in excellent stead. One gentleman from the United States actually responded in Russian to a "toast" at the dinner of one of the Sections, and you may imagine with what enthusiasm his speech was received.

It is a common impression, and probably a true one, that foreigners learn English much more frequently and thoroughly than we do their languages, and we are often given to understand that Russians are especially proficient in our tongue. So far as my experience went this is certainly a delusion, for I met with very few Russians who knew anything about English, though a comparatively small number had a smattering which enabled them to be of decided help, for which one felt very grateful. In this connexion I may mention that I have seen it stated in print, though I cannot personally vouch for the fact, that in the Sections "an English paper usually cleared the room, or nearly so, of all but English and Americans." Although it has been affirmed that we as a nation were not in particularly high favour at the Moscow Congress I cannot suppose that such conduct was intentional, but would rather take the more friendly view that it was the natural outcome of linguistic difficulties.

It was a very gracious act on the part of the Government to give members of the Congress "free passes" over their railways, nor would it be right to omit acknowledging the efforts which they made to guide and help benighted travellers on their arrival at the Russian frontier and at the railway stations of the great cities, as well as in their travels from place to place. That they were not always successful was due to circumstances over which they had no control. Russians of all classes are undoubtedly most civil, courteous, and obliging, and personally I was treated with the greatest civility and consideration at the frontier. With a good deal of lifting of hats and bowing the officials declined to examine any of my luggage. Unfortunately, however, this

experience taught me rather an unpleasant lesson, of which I give you the benefit, and that is not to trust too much in people who treat you with excessive politeness and suavity. As a matter of fact, my luggage was not sent on at all, but retained at the frontier owing to some little hitch in the matter of stamping, and I spent the greater part of my time at St. Petersburg, which I first visited on my way to Moscow in endeavouring to gain possession of it—a feat which I believe I never should have accomplished had it not been for the help of some most kind English friends. And here let me express my personal obligations, shared, I am sure, by many of my fellow countrymen, for the kindness and courtesy shown us by British subjects resident in Russia, both in St. Petersburg and Moscow, including his Excellency the British Ambassador, the Consuls and Vice-Consuls, representatives of the press, and private individuals.

On arriving at Moscow it was an immense relief, in the midst of the din and confusion, to be addressed in broken English, but sufficient for the purpose, by a most active, intelligent, and agreeable medical student, in neat uniform, who took charge of our party, speedily relieved us of all trouble and anxiety, and conducted us most comfortably to our destination. Indeed, throughout the Congress we found the students, ladies amongst them, most kind, attentive, and helpful, and I shall ever remember them with pleasure and gratitude.

I think that those who were present at the Moscow Congress are not likely to forget the "Manège" or "Palais d'Exercice," a huge building in which the "central bureau," with its various departments, was located. For those who had arrived fairly early and had got over their troubles without any great difficulty it was decidedly amusing to watch the frantic struggles of the seething crowd of applicants for tickets, badges, programmes, and general information. It so happened that at the time of the Congress a correspondence was going on in one of the London daily papers with regard to "overcrowding in the medical profession" and while there I came across some of the letters on the subject. It struck me, here was an object lesson of the fact with a vengeance! Between 7000 and 8000 members of the craft were gathered together and we were a motley crowd! There appeared to be representatives of almost every known more or less civilised nation or country and of every type of humanity. Need I say that we were also honoured by the presence of a considerable proportion of "lady doctors," who are quite an institution in Russia? If one ever felt dull or tired a visit to the "Manège" was always entertaining and interesting, but the time to see it at its best was during the period of the day allotted to "free lunch and drinks," with which we were most generously regaled for several days.

A striking contrast to the "Manège" was the "Assemblée des Médecins," where the "Comité des Dames" had a special bureau and a most delightful salon. Here everything was refined and restful. The ladies who formed the committee, some of them of the highest rank, were most attentive and hospitable, both collectively and individually, and exerted themselves to the utmost to contribute to the enjoyment of the lady visitors, for whose benefit their efforts were primarily intended, and to enable them to visit comfortably the various places of interest in Moscow and its neighbourhood. But their kindness did not stop here, for they never refused a helping hand to the gentlemen. In addition to a magnificent *soirée* the ladies had a most delightful introductory *réunion* on the evening before the Congress was actually inaugurated. Here might be seen Virchow, under the immediate protection of the Lady President, surrounded by successive relays of ladies, all eager to pet and do homage to the venerable pathologist. He appeared to be thoroughly pleased with himself and to enjoy fully his experiences, as well he might. Altogether, the ladies at Moscow raised a very high standard which it will be difficult to reach at future congresses.

Another scene which will live long in the memory of those who were privileged to witness it is that which was presented at the magnificent Grand Theatre Imperial of Moscow on the occasion of the first general assembly of the Congress and the inaugural ceremony which then took place. It must stand out as the most brilliant and imposing sight which has ever occurred in relation to the medical profession or is likely to occur in the future. I call to mind the opening meeting of the International Medical Congress in London, and it was a very poor show in comparison. I have not the descriptive faculty required to present anything like an adequate picture of the scene, even if time permitted me to launch out in this direction, and it must suffice if I mention some of its more prominent features. The Grand Duke Sergius presided on the occasion and the Grand Duchess with her suite occupied the Royal box. The stage or platform was thronged with the officers of the Congress, State officials, civil authorities, and leading Russian doctors, as well as with representatives of almost every nation. Many were of splendid physique and handsome presence. Magnificent and gorgeous uniforms of various kinds, civil and military, constituted a prominent feature of the scene, which was rendered still more brilliant by the display of medals and decorations on expansive breasts. The whole theatre was crowded with ladies and gentlemen, the former vying with each other in the splendour of their attire and jewels, and many of the latter being also clad in military or court dress. The large majority of us, of course, were not in uniform, but we were all dressed *de rigueur*, and here and there one saw the academic garb indicating a graduate of one of the Universities of Great Britain. It was extremely interesting to see in the flesh men whose names are to us household words and who deservedly hold high positions in our profession in various countries and cities. I will not weary you with any account of the proceedings and will only say that so far as the Grand Duke and the Congress authorities were concerned the speeches were commendably brief. I did, however, particularly note and take an interest in the general behaviour of the audience and their attitude towards the various speakers, to which I must just refer. In the first place I realised what is contrary, I think, to the general impression, that the Russians can applaud in the most vociferous and enthusiastic manner. The nationality of the speakers, undoubtedly influenced the fervency of the cheering; and as regards the speeches themselves, the points which elicited most vigorous applause were brevity, audibility, real oratory, which was exceptional, and the bringing to a close of a prolonged and tedious harangue. But what roused the audience to the highest pitch of enthusiasm was undoubtedly the personality of the speaker. Our old friend Virchow was greeted with a warmth which was both touching and catching. And here I hope it will not be considered out of place, or in the least disparaging to our distinguished representatives, if I give expression to certain feelings that took possession of me on this memorable and exciting occasion. I confess that I felt somewhat envious and jealous for my country and could not help being conscious of a keen sense of regret at the absence of one personality, who, I venture to affirm, had he presented himself on that platform, would have roused the audience to a pitch of enthusiasm which no words could describe or imagination picture. Need I say that I refer to Lord Lister? Among the great events of 1897 which had a special interest for the medical profession in this country will stand out conspicuously the elevation to the peerage of this most distinguished surgeon and teacher in the truest sense of the word. Not only was it the first honour of this kind conferred upon any member of our faculty, but it may be affirmed without fear of contradiction that the choice fell upon one who would have been universally acclaimed as pre-eminently worthy of the position. His brilliant intellect, his true genius, his devoted and untiring scientific and practical work, have achieved such vast and far-reaching results, not only in relation to the medical profession, but for the benefit of humanity at large, that the name of Lister is honoured throughout the length and breadth of this land; while he is revered and beloved for his single-mindedness, his straightforwardness, and his almost too modest demeanour. Not only so, but it is difficult to realise, except by actual observation, how he is positively worshipped by the medical profession in every civilised part of the world and to what extent his teaching and work have influenced and moulded the construction and practice of the modern great hospitals. Am I wrong in affirming that all of us who went to Moscow felt some degree of resentment at our Canadian friends who had enticed Lord Lister across the Atlantic, and that we should have experienced a deep and just pride had he been present to receive the ovation which would have undoubtedly been accorded to him by the united heart and voice of our continental brethren?

The excitement associated with the inaugural ceremony was too much for most of us to enable us to return after the interval to listen to the more formal addresses relating to professional subjects. So I cannot personally tell you anything about them. Nor need I refer to the second and third

general meetings, except to say that they presented a marked contrast to the first, although well attended, and that the proceedings were on the whole somewhat dull and tedious. The final winding up of the business, with its complimentary and farewell speeches and greetings, was decidedly trying to the feelings, especially when the President nearly broke down with emotion, and I have an impression that Sir William Mac Cormac, who, as I have already mentioned, occupied the chair, realised this very keenly.

It is not my intention to inflict upon you more than a brief reference to the sectional meetings and the work for which they were responsible. It must be acknowledged that the accommodation for these meetings was most excellent as regards the rooms in which they were held, these being in some instances quite magnificent, though their acoustic properties were not always everything that could be desired. The section to which I belonged met in the splendid ball-room of the "Assemblée de Noblesses," where in the evening social functions on a grand scale took place. The subjects dealt with in the various Sections appear to have been very much on the old familiar lines and on well-worn themes, and although no doubt the discussions were most interesting and instructive if one could have understood them, I do not suppose that they have brought us any nearer to a final settlement or agreement on any one disputed point. The audiences were as a rule remarkably good and a large number seemed to take a profound interest in the proceedings. On more than one occasion I was attracted by a crowd of eager listeners gathered round a speaker, evidently trying to drink in his every word, and applauding vociferously at the close of his remarks. I naturally concluded that he was imparting some extremely important and original information, but I always found that it was only some old subject that was being dished up, perhaps in a new way. I have no doubt the same venerable themes will be trotted out on similar occasions for many a day to come. Of course, different questions which have been attracting special attention within a recent period were brought into prominence and adequately dealt with, and for the discussion of certain special subjects two or more sections met, so that they might have the benefit of their united wisdom and experience.

It would be a great satisfaction and pleasure to me, if time permitted, to enlarge upon the kindness and hospitality lavished upon the visitors to the Russian Congress, not only by our medical brethren, but by the Czar and Czarina, the Grand Duke and Duchess Sergius, the municipal corporations, the committee of ladies, and others, in the way of banquets, fêtes, and entertainments provided for their delectation and amusement. To these, again, however, I can only make a passing reference and will say nothing as to private receptions or hospitalities. The public gatherings at Moscow were generally on a vast scale and some were truly magnificent, while the kinds of amusements provided were of a promiscuous character to suit different tastes and inclinations, including amongst others various descriptions of music, not always particularly agreeable to the ear, though interesting as illustrating Russian styles, and of course dancing. One of the most striking features of some of the entertainments was the enormous quantity and variety of foods and drinks provided in the way of refreshments. And a still more wonderful sight was the rapidity with which the tables were cleared of their good things and the extraordinary capacity which many individuals exhibited for accommodating any quantity of eatables and drinkables in every conceivable combination. Truly an instructive lesson in "dietetics" from a "medical congress" and by no means the first of a similar kind! I understand that those who went to St. Petersburg from Moscow were there regaled on the same magnificent and lavish scale, but as I was not one of the number I cannot speak from personal experience or observation.

Amongst the entertainments provided for us at Moscow there were two to which I feel bound to particularly refer for a moment. The first was a "religious concert" given by singers of "L'Ecole du Synode." Such a combination of male voices, especially basses, and such superb singing it would be almost impossible to equal, and I think I may say for those who were present that this concert was an immense treat and gave us a very exalted idea as to what Russian music is capable of. The other was the delightful garden party given by the Grand Duke and Duchess Sergius at the Alexandrina Palace on the Friday after the Congress was really over to console those who could not get away owing to a failure of train accommodation and to try to make their enforced stay pleasant and agreeable. Those who were thus circumstanced had no reason to regret it, for a more enjoyable as well as refined function of the kind I never remember. Several bands discoursed splendid music; the refreshments were really beyond description; and the cordial personal welcome with which their Imperial Highnesses received their guests, chatting with them affably and without any restraint or reserve, produced a pleasing and grateful impression which, whatever happens, can never be effaced. This gracious act of hospitality on their part formed a delightful and most soothing conclusion to the Moscow Congress.

In an earlier part of this address I intimated that I might feel myself at liberty to refer to matters not immediately connected with the Congress itself, and now, Mr. President and Gentlemen, I do not offer any apology for troubling you with some remarks about Moscow and may drag in incidentally certain points relating to Russia as a country and the Russian people, as well as to questions with which we are more immediately concerned. To the medical profession the conditions of great cities must always present interesting and attractive features and the comparison of foreign cities with those in this country affords much food for thought and reflection. The problems that constantly face us, and with which it is a main part of our duty to attempt to grapple, are not only extremely important and difficult to deal with, but often exhibit a most appalling and tragic aspect. The ideas entertained by the mass of our people who have never ventured beyond these shores with regard to other nations, are generally as amusing as they are narrow, insular, and erroneous, and they would be very much astonished if they were told that London by no means always compares favourably with many foreign cities, even in countries which are supposed to be mediæval and essentially backward in civilisation. I think those of us who went to Moscow had our eyes very much opened on this matter and many of our preconceived notions and ideas were rudely swept away, while others were greatly modified and corrected. We would be inclined to agree with Sir Wemyss Reid, who in an interesting article in the *Nineteenth Century* entitled "First Impressions," gives an account of a visit last autumn to St. Petersburg and Moscow, amongst other cities, and expresses himself as quite taken aback by what he found in the latter city. He writes: "I had thought of it, as I imagine most of us do, as the decaying capital of that older Russia which is passing into the stage of tradition—a sleepy, old world city where ancient customs and national usages still survived and little beside was to be met with. I found it a huge city numbering nearly 1,000,000 inhabitants, where side by side with the traditional usages of old Russia and, above all, its external devoutness of carriage and demeanour, is to be found the most marvellous development of industrial and commercial enterprise and activity. The streets were as crowded and as full of bustle and life as those of London or Manchester; the groves of tall factory chimneys enveloping the suburbs reminded me of Birmingham. The markets were filled to overflowing both with merchandise and men. The shops were certainly not inferior to those of St. Petersburg and everywhere there was the bustle, the unending activity which bespeaks the existence of a great community engaged in the full work of life. It was only slowly that what I saw enabled me to realise the truth about Moscow—the truth that it is no city of the dead, no relic of mediæval times, but the living capital and centre of a mighty nation, which, though it may wall itself in against western ideas and manners, has an overflowing life of its own and an energy which it is expending freely in a thousand different directions. Those who seek to realise what Russia really is and what enormous potentialities of growth and development she possesses within herself must go to Moscow." Of course, this general aspect of Moscow naturally interested the visitors to the Medical Congress, in common with others, but what could not fail to prove specially attractive to them was to observe the marvellous progress and the immense strides which have been made in scientific and practical medicine, and the remarkable developments in the way of hospitals and institutes for the study and treatment of disease from every conceivable point of view. I think I am expressing the general feeling when I say that not only were we vastly astonished, but some of us were consumed with envy, for we could not conceal from ourselves the fact that in many respects even Moscow, to say nothing of St

Petersburg, is medically and surgically far ahead of this great city of London, with its boasted advanced civilisation. The magnificent and splendidly equipped Clinical Hospital at the Dievitchie Pole, with its separate buildings for every department of medicine and surgery gathered together in one place, on an area of between fifty and sixty acres, and constructed on the most approved and advanced sanitary principles, was a revelation to us all of what Russia is capable of. Here were to be seen every kind of modern appliance for clinical investigation and treatment; while there were special institutes set apart for the study of pathology, bacteriology, pharmacology, and other branches, with every possible modern requirement for scientific investigation and research. What a magnificent field and what an infinite mass of material of every kind for clinical instruction and study, all arranged and classified in the most admirable manner for immediate use. I confess that I could not help contrasting, to our decided disadvantage, this methodical arrangement with our numerous scattered hospitals, where so much valuable material for clinical purposes is absolutely lost, and such excellent teaching is often wasted, or at any rate does not produce its legitimate results, from a want of proper concentration and organisation. With regard to investigations and researches which have for their sole object the advance of medical science and art, need I say that the disabilities which hamper our profession in this country must, while they last, be a continuous check on progress and discovery, and a constant source of resentment and indignation, when we contrast the conditions under which our scientific men work with those which prevail in Russia and other countries, where ignorant, self-seeking, or sentimental faddists are not allowed to have their way, or by their gross and calumnious misrepresentations to mislead the public as to the nature as well as the aims and intentions of the investigations carried on in relation to medicine and surgery by men who have for their paramount aim the well-being of humanity and the relief of suffering. Nor are they at the mercy of a certain class of so-called "statesmen" and "politicians," I care not to what party they belong, who, in order to catch a few votes, will support any outrageous measure which has for its purpose the prevention or stamping out of rational and legitimate scientific research, and who, when it suits them, treat the medical profession with the utmost contempt.

The subject of operative surgery hardly comes within my province as a physician and I should not refer to it at all on the present occasion were it not for a personal experience when at Moscow which I suppose I ought to have looked upon as a special treat. Speaking generally, I think I may say that the operating theatres in the Russian hospitals are equal in every respect to anything that can be found in any part of the world, while the thoroughness and perfection with which antiseptic and aseptic methods are carried out leave nothing to be desired. Nor could one fail to be struck with the vast number, variety, and ingenuity of the instruments and apparatus for operative as well as other purposes which were exhibited for our inspection. There are also private hospitals in Moscow where operations of various kinds are performed and these seem to be equally well provided with every modern requirement. Whether such institutions should be imitated or encouraged may, however, be a matter of opinion. It was at one of them that the experience to which I have referred took place. Purely out of kindness and as an act of hospitality I was invited to a "private view" of an exhibition of "cerebral surgery." Mr. President and Gentlemen, I did not enjoy it, curiously enough, and as soon as possible made my way out of the operating theatre. I was met by what I can only describe as a mob of men and women who nearly crushed me in their struggles to gain an entrance into the theatre, and when it could not contain any more those who were left outside crowded round windows where they might possibly catch a glimpse of the public display of operative surgery which was now about to begin. My hurried flight from the scene prevents me from giving further details. This scene and the loud applause which I heard on another occasion at the close of some brilliant operations at the Clinical Hospital, and which was rather a shock to one's feelings, gave form and expression to two thoughts which have for some time been vaguely floating in my mind, and which I only dare venture to suggest here in the presence of eminent surgeons with the profoundest respect and humility as well as with fear and trembling. In the first place, is it not just possible that with the immense advantages and facilities possessed at the present day for the performance of formidable operations of various kinds, with the aid of anæsthetics, antiseptics, and suitable instruments of every description, and the truly marvellous skill which surgeons have acquired in numerous directions, there might be a tendency to perform such operations on insufficient grounds and more frequently than is actually warranted by circumstances? Then I do not think the fact can be denied or blinked that there exists rather widely a morbid desire or craving to witness what may be fairly termed "sensational operations," or, at any rate, to be present at them, even when it is impossible actually to see any part of the procedure. Such an operation proves so attractive to the modern medical student that it will practically empty the ward or the lecture theatre, and not the most brilliant or popular clinical teacher or lecturer can entice him from the scene or bring him down to the level of the humdrum subjects which he will have to face at examinations or with which he will have to deal in the ordinary practice of his profession. Up to the present I am glad to think that applause after operations, however skilfully and brilliantly performed, would not be tolerated in this country, and I hope it never will be. It would be a mournful day when that consideration and respect for human life and suffering, which have been the glory and boast of the medical profession from time immemorial, should ever be weakened or lost, or when there should arise the least ground for the suspicion that the surgeon's art aimed in any way at rousing the mere admiration of the lookers-on or appealed in the slightest degree to the modern craving for excitement and sensation.

The remarkable institutions which are met with in different places in Russia, but which have reached their highest development in Moscow, known as the *Maisons des Enfants*, or Foundling Hospitals or Homes, present many points of interest to the medical profession and I cannot pass them by altogether without notice. Their history and objects are well known, or at any rate can be gathered from any of the books written as guides to Russia. It was a strange notion of an extraordinary woman—the Empress Catherine II.—to found an asylum or home for illegitimate children, and whatever the motives might have been which prompted the idea it cannot be said that its outcome has tended to promote morality or that the "great care and devotion to infants born to shame and poverty is the highest form of development of rational philanthropy," as Sir Wemyss Reid well puts it. It means the "preservation every year of thousands of lives to swell the great army of want and suffering." The mortality, however, is very high, for which one really cannot help feeling thankful. The number of annual admissions into the Moscow institution now exceeds 17,000 and the history of its progress clearly demonstrates that its establishment has vastly encouraged illegitimate child-bearing. When paying it a visit, although one could not help being deeply impressed with the marvellous extent and character of the work, the excellence of the arrangements, sanitary and other, the general air of well-being and comfort, the kindly and sympathetic behaviour and actions of all the *personnel*, and especially the thoroughly systematic methods adopted under medical supervision to sustain life and to protect against disease, the sight was not a pleasant one, either from the side of the infants or the mothers, who are practically the nurses and who certainly did not give one a very exalted idea of Russian women or girls, for a large proportion of them were quite young. Indeed, I agree with Sir Wemyss Reid that it was a "painful spectacle," though at the same time one full of pathos. A particularly objectionable feature to witness was the number of wretched specimens of recently-born infants which they were endeavouring to "incubate" into life. And the sight reminded me that even in this country "human incubators" are just now assuming a disagreeable prominence. It is a dangerous topic to venture upon as to how we should deal with new-born infants who are obviously destined, if they survive, for a life of disease and probable suffering and in whom the spark of vitality is smouldering to extinction. I yield to no one in my respect for human life and in my tender sympathy and affection for children, but it has sometimes struck me that our efforts to sustain existence under such circumstances as I have just referred to and others are not always in the direction of true kindness towards the poor little souls. At any cost I will go so far as to say that if an infant needs an incubator to launch it upon "life's tempestuous sea" such an apparatus ought never to be

employed without the most conscientious thought and consideration, and its use always demands the utmost rational discretion. To exhibit an incubator in active work upon a human life in places of public entertainment, which is one of the attractions offered nowadays, does not tend to raise one's estimate of modern humanity and is only another example of the morbid craving for some new excitement which prevails so widely at the present time.

I do not intend to speak about the remarkable sights at St. Petersburg and Moscow, with their environs, in the way of palaces, gardens, museums, churches, and monasteries, except to make a brief allusion to the churches generally and the religious aspect of the people. The costly splendour and magnificence of many of the churches are beyond description, but one could not help feeling that much of the wealth thus lavished might have been better employed in other ways. The Kremlin was of course a constant centre of attraction and interest, but some of its churches are more curious than beautiful. The services are highly elaborate, spectacular, and impressive, and the ritual is gorgeous and dramatic. The earnest and devout reverence of the people of all classes, their fervent acts of worship, and their devotion to their religious ceremonies and practices, both within the church and outside, were most remarkable and sometimes bordered on the grotesque. They seemed to have a profound and unwavering faith which to an outsider appeared hardly distinguishable from the most abject and ignorant superstition. There were two features in which the churches presented a marked contrast to those of this country. There was an entire absence of seats and everybody had to stand except when they were engaged in the act of kneeling or prostrating themselves on the floor. Then there was no distinction of persons, but the rich and poor, the well dressed, the working man, and the ragged beggar were all massed together in one common and miscellaneous crowd. I must say that the experience was by no means always pleasant, especially when there was a crush. The odours emitted were certainly not the "odour of sanctity"; and one could not but feel conscious of the special facilities afforded under the circumstances for the conveyance from person to person, not only of infective microbes, but of more easily recognised entomological specimens. A very tragic illustration and object lesson of the possible state of things in a Russian church was afforded by a terrible event which has been reported in the newspapers since the Congress. A consecration service was being held in a crowded village church when a panic was caused by the cries of "fire" and "help" from the outside. Of course the worshippers crushed towards the door, the result being that 74 persons were killed and 160 more or less seriously injured. There was no fire, but as the ventilators had not been opened at first it became necessary to throw open somewhat suddenly both ventilators and windows, whereupon dense clouds of vapour issued forth from the steaming congregation within, which was mistaken by the crowd outside for smoke, especially as at the same time a blaze of light was produced by the lighting up of all the candelabra. To an outsider religious life and practice in Russia certainly do not present an attractive aspect from a medical point of view, and they can hardly be regarded as contributing to the physical or moral well-being of the people. Nevertheless, during the comparatively recent so-called "agreement" between Russia and China it was rather amusing to read in an extract from an article in a St. Petersburg paper that Russia was going into China as "the standard-bearer of Christian culture and civilisation." I wonder how the Chinese will like it!

The problems that present themselves in relation to great cities as regards their material, sanitary, social, and moral conditions and the evils to be contended against are in the main common to all and are but too familiar to us as a profession in this vast London. Taking a comprehensive view of our metropolis and comparing it with foreign cities I can only give vent to my own feelings by saying that it is a most contradictory, inconsistent, aggravating, and tantalising place. No one can deny for a moment that, apart from its unavoidable climatic drawbacks, it has attractions and advantages which can be found nowhere else; and some of these come into conspicuous prominence after a visit to such cities as St. Petersburg, Moscow, and Warsaw. Amongst others one seems to breathe a freer air and to be relieved of an indefinable vague sense of unrest, insecurity, and danger, which amidst all the courtesy and kindness shown to us I think many visitors to the Congress could not help feeling conscious of when in Russia. It may be a question indeed whether freedom in London, in common with every other part of this country, is not carried rather too far and whether sometimes "liberty" is not allowed to degenerate into "license." The fact cannot be ignored that not only in London but in many other cities and towns within this realm rowdyism, ruffianism and acts of robbery with violence in our public streets, even in broad daylight, are greatly on the increase, so much so that one of the metropolitan magistrates spoke strongly not long ago about what he called a "reign of terror" in his district. I really think it is safer to walk in the streets of St. Petersburg or Moscow than in many parts of this city. Moreover, whether we are doing the right thing in permitting indiscriminate alien immigration to the extent which is at present the rule is a matter for serious consideration. Apart from other aspects of the subject I have been recently informed on reliable authority that in certain districts, not in the "east-end" either, they have to be constantly fighting against the most disreputable characters, who pour in chiefly from Russia and Poland, and who manage to get possession of houses of ill-fame as rapidly as they are closed, carrying on the most nefarious practices and being an intolerable nuisance and curse to the neighbourhood. Surely such a state of things ought not to be allowed to continue for one moment, and it is but fair to the inhabitants of London that some discrimination should be exercised as to the kind of people who are welcomed into our midst. And in this connexion I cannot refrain from uttering an energetic protest against a crying evil which constantly stares us in the face in this immediate vicinity as well as in other districts, and which has reached such a pitch that even the clergy are roused to denounce in the daily press what they rightly term "a grave scandal." I allude to the extraordinary laxity shown by the public authorities in permitting the most shameless and repulsive women to parade our principal streets and thoroughfares in open day, especially at the time when they are most frequented, to flaunt their calling in the most ostentatious manner and to molest passers-by with their solicitations. Most of these creatures are also obviously of foreign importation and what they must think of a great city which actually seems to invite them to a line of conduct which would not be tolerated for one instant in any other civilised city in the world I really cannot imagine. Efforts are being now made in many quarters to promote purity, and not only have we the most cordial sympathy with such efforts, but we must not mince matters, and it is time for us to speak out plainly and boldly. Let us be consistent, however, and practise a little common sense by doing our utmost in the first instance to put down temptation in every form. We shall have no difficulty in emphatically endorsing a resolution passed at a recent influential meeting held at the Guildhall in connexion with a "special crusade" against gambling, intemperance, and impurity calling for immediate action on the part of all good citizens and of the Legislature with a view to effecting, amongst other reforms, the "promotion of energetic action on the part of the police authorities for the suppression of street solicitation." In one of the letters emanating from the clergymen already referred to they say: "We are more than ever persuaded that the time has arrived when the properly constituted authorities should take the needful steps to remove an evil which is a decided blot upon the social system of a great Christian city." This seems to me to be an exceedingly mild way of putting the matter. They are more practical when they write: "May we not also reasonably expect that the evils to which we directed attention (in a previous letter) may induce some action on the part of the public authority to protect passengers of both sexes from interference whilst they are making lawful and proper use of the public thoroughfare." The Bishop of London, speaking on the "Promotion of Purity" at a conference held not long ago, remarked that it was always possible to get a high-minded and God-fearing physician who was ready and willing to speak to men—and, above all, to young men—about the temptations to which they would be exposed, and whenever this had been done in his experience it had always been productive of the best results. This, no doubt, is true, but I fancy there are few of us who possess the qualifications necessary for carrying out such a work successfully and efficiently. We can all, however, unite in expressing our utter condemnation of the existing state of things in the capital of this great country, and I have thought it my duty, as fairly coming within the scope of my subject, to give vent to what I venture to believe must be the unanimous feeling and sentiment of this

Society and of the medical profession at large with regard to a grave and pressing evil, and to join others in strenuously urging upon our public authorities, whoever it may concern, the imperative necessity for immediate and radical reform, in order to sweep away a scandal which is not merely a "blot upon the social system of a great Christian city," but which must sap the very foundations of decency, morality, and order in any civilised community.

The question of intemperance is a very pressing one in Russia and it was interesting to meet in Moscow a few who, like many temperance reformers in this country, strive to influence those with whom they come into contact by their personal example, being strict total abstainers. I have recently seen an announcement that the enormous increase of intemperance has led the Russian Government to take the question into its own hands and as a first step the sale of spirits in the country is gradually being turned into a Government monopoly. The Government is also directing its attention to counter attractions to the public-house and has appointed a "temperance curatorium" in St. Petersburg, one of whose duties is to provide these. Here is a useful hint to our legislators and to the authorities who have to contend with the same evil in this country. It seems to be a general belief that drunkenness is far more prevalent in Russia than amongst our people, but from what I have seen and heard I am not at all sure that there is any real foundation for such a notion. At any rate, we cannot boast that the inhabitants of any part of the United Kingdon are models of temperance and we are not in a position to throw stones at any other nation. The sights that constantly obtrude themselves upon us in London, even in the "West-end," are disgusting and appalling, and I confess that they often produce in me a feeling of profound humiliation as well as of utter impotence, hopelessness, and despair. And yet how can we wonder at the state of things when we observe the temptations and attractions presented on every hand, as contrasted with the so-called "homes" of the people, in the shape of luxurious public-houses, which almost vie with the Russian churches in their gorgeousness and magnificence. It may be interesting to note that the Russian working-classes appear to be much more methodical in their drinking habits than our people, with whom, by the way, they compare by no means unfavourably in appearance and manners, so that the effects of excessive indulgence may not interfere immediately with their regular employment, and I fancy that the Government has something to say in this matter also. Judging by current events it does not look as if the drink traffic in this country is likely to be controlled or checked in any way for many a day to come. This is easily explained, not only by the inherent sentiment planted in the breast of every "true Briton," that he will never, if he can help it, permit what he calls his "liberty" to be interfered with, but also by the powerful individuals and combinations of persons who are directly or indirectly interested in this traffic, by the enormous fortunes and large dividends which it yields, and by the too tempting contribution which it makes to the revenue. It must be acknowledged that this state of affairs does not strike one as being altogether satisfactory or gratifying. I certainly am no advocate for entering upon the impossible task of trying to make people sober "by Act of Parliament" or any other compulsory method, except in the case of habitual inebriates, nor should I like to see any meddling interference with fair dealing in alcoholic drinks, but as medical men we cannot shut our eyes to the practically unlimited facilities and encouragement given for the abuse of alcohol and the establishment and continuance of intemperate habits, not only in this city, but in the country at large, and of the terrible consequences resulting therefrom. Here, again, surely "liberty" has been allowed to degenerate into "license" and it is our duty so far as lies in our power to support every rational measure which has for its object the promotion of sobriety, coupled with a due recognition of the established and legitimate rights of those who deal in articles of commerce which, when used intelligently and in moderation, are, in my opinion, not only harmless but capable of contributing in no small degree to the comfort and well-being of the human race.

I have thus far been dealing with the more glaring evils in this city and country which a comparison with Russia brought prominently before my mind, but I must still note some minor points in relation to London in which we are lamentably deficient and where we might learn many a valuable lesson from other capitals. The causes of these defects are many and various, but they are obvious enough, though at the same time by no means easy to overcome. Amongst them may be mentioned the obstructive influences associated with long-established "rights and privileges," vested interests, monopolies, and corporations; conflicting opinions and interests of official bodies; a complete want of any comprehensive or controlling organisation; feeble and often ignorant though thoroughly self-satisfied vestries; general apathy and an indisposition to make any effort against existing abuses, but to let things slide—a failing to which we are all very prone; individual self-seeking and absolute selfishness, without a spark of consideration for others; and, I have a strong impression, no small amount of "jobbery," as well as "bribery and corruption," in many directions. There can be no doubt that the laws and regulations intended to benefit the community at large are often tacitly ignored or even treated with open contempt and defiance; and it has struck me that a short experience of autocratic government might do us no harm and help to put matters right. Comparing London with Moscow I have been told on good authority that the latter is about the most insanitary city in the world and I can quite believe it. Certainly one could not help noting a general objection to fresh air and ventilation and as a rule an absolute neglect and disregard of all sanitary conditions, precautions, or regulations. In these respects no doubt we are on the whole far in advance, not only of Moscow, but of many other cities, though there is still much to be desired. Indeed, have we not frequent revelations showing that not only in London but in many other cities and towns, as well as in rural districts which nature has made lovely and beautiful, the most elementary sanitary laws and conditions are absolutely ignored, and if the descriptions given are true we have quite recently had brought prominently under our notice in the press a state of things in one of the neighbouring counties which can only be fitly characterised in the words of the *Times* as "grave scandals" and a "disgrace to civilisation and humanity." Taking a superficial view of things Moscow appeared to be decidedly cleaner than London and as for the lighting of the streets we are not in it. Indeed, I am afraid that our metropolis has an unenviable reputation for being dirty and badly lit, and our friend and would-be reformer *Punch*, in his last Christmas number, includes among what he calls "Some Christmas Waits"—"A system of illumination and purification of the London streets which shall be at least equal to that of the second-class European capitals." Those of us who reside in this locality are thoroughly familiar with these two defects, but we must not altogether hide our light under a bushel, for there is one example of strenuous if misdirected energy which really deserves publicity, though I must say I have witnessed the same performance in Moscow and other places. We must not, however, withhold the honour specially due to London and to the Marylebone Vestry and sanitary authorities in particular. Given a series of wet, filthy, muddy days, the streets are left absolutely untouched and even the professional crossing-sweepers are then generally conspicuous by their absence. To cross Portland-place or Harley-street, for example, under such circumstances is an experience neither good for the "outward man or woman" nor for the temper. But let there come an absolutely dry day, with a high wind and heaps of dust, mixed with an abundance of desiccated excrement and expectoration, and then you will find some ten or a dozen lusty men vigorously sweeping these and other thoroughfares and choking the passers-by with the volumes of a choice and miscellaneous assortment of microbic and other abominations which they raise by their efforts. The *rationale* for this performance is not evident at first sight, but it has occurred to me that it might possibly be intended to promote the interests of the medical profession in this neighbourhood by exciting disease and spreading infection, as a slight return for our help in so greatly enhancing the value of property and our large contributions to the Imperial taxes and the local rates!

There are other aspects from which London might be fairly criticised even as compared with Moscow and other cities supposed to be far behind in civilisation, but time warns me to forbear. I will only mention the matter of overcrowding, which is further so often associated with obvious and sometimes the most revolting insanitary conditions, which ought not to be permitted for one instant. All this, of course, is perfectly well known in a general way, but the disclosures made from time to time in the newspapers, especially in connexion with inquests, are truly shocking and appalling. In

the course of a discussion a short time ago my friends Dr. Corfield and Dr. Poore both agreed in letters to the *Times* that the huge infant mortality in London is mainly due to overcrowding. Surely this state of things might easily, and ought to, be kept somewhat in check at any rate, and Dr. Poore well writes: "Is it not time to do something to try to arrest the overcrowding in London instead of regarding it with complacency because there happen to be more unhealthy cities elsewhere?" Whether the solution of the difficulty advanced by this eminent authority in sanitary matters is correct or not I do not feel competent to judge, but my impression is that the millennium is not yet in sight and will not come in our day.

I hope, Mr. President and Gentlemen, that I may not be regarded as having gone beyond my province in the preceding discussion of some of the aspects of London with which we as a profession are immediately concerned and in which we have a direct interest. I hold it to be our duty on every possible occasion to bring prominently before the public any glaring scandal or abuse as well as minor imperfection in our social system which tend seriously to impair the health or to interfere with the well-being of the community at large, without regard to class or station in life. Personally I felt that this was a legitimate opportunity of which I might justly take advantage. Not that I flatter myself that my remarks will have the slightest practical outcome or effect. Things will go on just as before and we must merely await as patiently as we can the results of enlightened progress. I know not whether we are to be governed in the future by the "county council" or by separate "municipalities," nor do I feel competent to express any definite opinion as to which is the better method. We can only trust in Providence and hope that, to whatever body or bodies may be entrusted the control and guidance of our affairs, they will bring to their great and noble task intelligent thought and consideration, founded on due knowledge and experience, honesty of purpose, and an earnest desire for the welfare of their fellow citizens.

Mr. President and Gentlemen, this is the age, amongst other characteristics, of vast association meetings and congresses of all kinds—national and international—and the questions have been raised whether these gatherings are of any practical value whatever or serve any really useful purpose and whether they should be maintained? I have read some particularly disparaging comments with regard to their social developments and they have even been compared to "huge picnics." So far as International Medical Congresses are concerned, although for obvious reasons there is no actual necessity for them at the present day, yet it would be a pity to abolish them altogether. If they do nothing more, they may possibly form a link to bind nations and peoples together in unity and concord and to promote peace, it may be, when "relations are strained." But, further, my own opinion is that while they certainly are capable of working infinite mischief, on the whole they do a tolerable amount of good in the way of guiding the profession generally into right channels—sometimes at critical epochs; of promoting and developing that which is worthy of encouragement and support; of bringing into prominence novel discoveries relating to the science or art of medicine and surgery which are of real merit; and, on the other hand, of keeping in check, or entirely suppressing if need be, any tendencies which are detrimental to the true dignity and advancement of our profession or to the practical interests of those with whom we have to deal as patients. As regards the Moscow Congress, from what I have previously stated, it may be gathered that its outcome has not led immediately to anything very remarkable or striking. It was not, so far as I know, signalised by any unusually brilliant or sensational incident from a medical or surgical point of view or by the announcement of any startling discovery. For this I feel personally profoundly thankful, for my firm impression is that the medical profession has at the present time quite enough material for investigation and study to engage the attention and best efforts of its most able and energetic members for many a day to come. Nor, I am glad to say, did this gathering afford any undue encouragement to certain modern ideas and tendencies which cannot fail to give occasion for anxious thought, not unmixed with foreboding, to those who have the true interests of our vocation at heart.

After some hesitation I have come to the conclusion that my text fully entitles me to call attention to some of the more pronounced of these tendencies and to offer a few comments upon them, which, of course, only express my own personal views. In the first place there is the now somewhat stale question of "specialism," which is always with us, but the process of "splitting up" is still going on, and where it will end it is impossible to say. I will merely remark that it has already reached a pitch which can only be described as ridiculous and absurd, and that the incalculable mischief which it is working must be obvious to any rational and disinterested observer. Then there is the tendency which undoubtedly exists to run certain branches of medicine almost entirely on so-called "scientific" lines with little if any regard to their practical relationships or bearings. This is all very well for gentlemen who spend their days in the calm retirement of some quiet laboratory, enjoying the satisfaction and delight which scientific research, with its marvellous results and achievements, must always afford. But it is a very different matter for the active practitioner or physician who has to study and combat disease in its manifold manifestations and combinations in actual living patients, with all their personal idiosyncrasies and individualisms. The tendency is also evident in the education and training of medical students at the present day, for whom the more scientific branches of study naturally possess decided attractions. It will be an evil day, however, for the medical profession should this tendency be unduly encouraged or developed, or should those who are preparing for its active duties be taught to ignore or make light of its more practical problems and aspects.

No one who has watched the progress of events can fail to be struck with the advances and remarkable discoveries which have been made during recent years in the science and art of therapeutics. This very fact, however, has led to certain developments, for which we as a profession are more or less responsible and which are even now doing much harm, while they give occasion for serious anxiety as to the future. In the first place there are the extraordinary ideas now so widely prevalent with regard to supposed "cures!" I have even met with medical men who have rather wild notions on this point, but I hardly imagine that any rational and honourable member of our body would go quite the length which a very large proportion of the laity have reached. Their views are that a patient invariably suffers from some disease as a distinct entity, that every such complaint must have its cure, and that it is our business to find it out and practise it. Hence they are ever on the look-out for some sensational discovery or some novel line of treatment which shall serve the desired end in relation to this or that complaint. If one is not "up-to-date" with regard to the newest and most recently advanced "cure" for the more familiar diseases—for example, typhoid fever, influenza, or phthisis—and unless one is acquainted with every "advertised remedy," generally recommended by some individual of no scientific or professional standing or, it may be, utterly unknown to fame, he is looked upon as being "behind the times" and only fit to be shelved. I can affirm from personal knowledge that not a few have a fixed idea that when we go to a Medical Congress our object is to bring away with us, actually or potentially, definite "cures" for various complaints, the outcome of the collective wisdom of those who take part in its discussions, and they cannot understand otherwise what business we have there at all. As intimately associated with this idea comes the bewildering succession of new therapeutic agents with which the drug-market is being constantly inundated and with every one of which we are expected to be familiar. No doubt many of them are useful for particular purposes, but very few become permanently established as really valuable remedies. Another most mischievous practice to which we cannot shut our eyes in these days is the tendency to run some special line of treatment which happens to be "the fashion" at the time for every case belonging to a certain class of diseases, without judgment or discretion or any rational consideration as to its appropriateness in individual instances. I have found by bitter experience that unless you are prepared to fall in with the prevalent views and to advise or practise such treatment under all circumstances, even against your better judgment, conviction, and conscience, the public will have none of you, and again you are delegated to a "back seat." To sum up the whole matter, patients and their friends have been taught to believe that no matter what the conditions may be with which the medical practitioner has to contend, modern science and skill ought to be able to cure them straight off, or at any rate to relieve their

sufferings under every possible combination of circumstances, and they as a rule expect that these results can be achieved by a mere "prescription" or a "bottle of medicine."

There is still another tendency to which I must refer and which, if persisted in, is likely to lead to more and more trouble as time goes on, and that is the temptation to give expression and utterance to prophetic assertions, predictions, and promises with regard to prolongation of life, eradication of disease, marvellous improvement in the health of individuals and communities, and so on. For the world at large the outlook is truly rosy, but for the medical profession it is black indeed, seeing that its members will "have no work to do" and in process of time it must inevitably become extinct. It goes without saying that every one of the infectious complaints will be completely routed and annihilated even within a short period, and in the meantime every human being shall be so inoculated as to be rendered immune against the whole lot. Gone will be the days of "stirring epidemics of influenza to blow big dividends" to a certain company! I have seen a statement in print that two of the most eminent authorities in our profession, gentlemen for whom I have personally the highest esteem and respect although compelled to differ from them, have expressed their firm conviction that pulmonary phthisis will be eradicated—one says within 200, the other within 50 years. I have often been amused as well as amazed with the glowing prophecies made in irresponsible lay newspapers and periodicals or journals and with their almost hysterical outbursts about the "advances of science," the "marvellous achievements of medical skill," and similar "tall talk." That does not signify, however, very much and we cannot prevent such effusions. But when the influential medical press indulges in the same theme beyond what is strictly in accordance with facts, or when some well-known and prominent scientist or physician paints a radiant picture of what is going to happen even in the near future, it is a very different matter. The laity naturally believe them and pin their faith on their statements. Then follows disappointment, not unmingled with resentment, that the predictions do not come true and that the millennium does not arrive. And yet, Sir, it does not. The contagious affections are still amongst us and in full force, and we are from time to time startled by the breaking out of a virulent epidemic of some grave disease of this nature which we had flattered ourselves had been practically exterminated and which we find it almost impossible to check or to cope with successfully. And this does not result from any want of knowledge as to how to deal with these complaints and how to prevent them, or of devoted skill in treatment, but from the mere force of circumstances which are obvious enough. The fact seems to be that those who make what I must term rash predictions do so from an entirely theoretical, scientific, or "laboratory" standpoint. They appear to forget altogether the inevitable conditions of existence and social life, among civilised perhaps even more than uncivilised communities, and they also ignore entirely such factors as human weakness, appetites, lusts, passions, and selfishness. Do not let us be led away with exaggerated ideas and expectations and imagine, for example, that because the tubercle bacillus has been discovered such a disease as pulmonary phthisis will soon be a thing of the past. We may strive as a profession, as we do, to our honour be it said, to promote the adoption of every preventive measure at our command, we may go so far as even to try to stop people from kissing, as well as expectorating just when and where they please, but I venture to predict (and at any rate I am safe in doing so, seeing that no one now present will have the chance of contradicting me when the time comes) that so long as the world lasts consumption will still be one of the chief scourges and dreads of its inhabitants.

In the preceding remarks it has not been my intention to say one word against rational progress in relation to the subjects which I have discussed, or the adoption of any method or measure which can be of real service for purposes of clinical investigation and diagnosis, or for the prevention and active treatment of disease. By all means let us do all in our power to promote sound health and the general well-being of humanity and to encourage them to take a hopeful and optimistic view of the future, so far as is consistent with common sense and actual hard facts. But let us never forget that we have to protect our patients and fellow-creatures against themselves, if I may so speak, as well as against numerous dangers from without. A moment's consideration will show that the tendencies against which I have been uttering my feeble protest afford direct encouragement to, and open up unlimited opportunities for, charlatans and quacks of every kind. We must charitably assume that there are none actually within the ranks of our profession who come under this category, and yet it now and then happens that the General Medical Council find it necessary to remove from the Register one of its members for downright and unconcealed quackery. Not that in the scandalous and at the same time humorous state of our laws with regard to practitioners of medicine—as contrasted with the legal profession, who take very good care of themselves—it makes the slightest difference to the individual so expelled, unless it be in his favour, for he can go on just as before, or even with additional *kudos*, posing as the victim of professional injustice and jealousy. And then comes the matter of advertisements. Really, Sir, what is the use or advantage of any Congress or even of this venerable Medical or kindred Societies, with their regular meetings, reading of papers, and learned discussions, when in almost any lay, not to mention pharmaceutical or medical, paper you will find not one but any number of "cures" and "remedies" recommended for every possible disease or symptom, now frequently with the additional attraction of the photographs of grateful patients before and after treatment? Even such a journal as the *Times* sometimes inserts advertisements of which I hardly think those who are responsible realise the significance. Not long ago I cut this advertisement out of the most prominent column on the front page of this leading newspaper: "Dr. [a foreign name, but not Koch] has discovered the Bacillus of Tuberculosis and is able to heal this malady." Then we are informed that "the Court Physicians" prescribe a certain preparation for our "Royal Family" which of course has the power of curing every "ill that flesh is heir to"! But of all the advertisements, usually supplemented by the most flagrant and grotesque "puffs," which are a scandal to this country and to the present "enlightened" age, none approach within measurable distance in barefaced impudence and downright misrepresentation those found in much of the so-called "religious" or "Christian" press! These papers wholly belie in this respect the titles they have appropriated and make one feel almost ashamed of words with which we are accustomed to associate all that is true and great and noble. They are more especially the means of propping up and foisting upon the public that particularly offensive species of the genus "quack" who under the guise of religion and religious motives is allowed by our laws to prey unchecked upon ignorant and confiding simpletons by pretending to have discovered a "specific" for some grave and widely-distributed malady which he will dare to hold out as a "certain cure" even at the last extremity, when death is at the very door! I affirm that which I have actually seen. No wonder such creatures amass large fortunes. These advertisements and puffs are then passed on to some of the so-called "Society" papers, and so the game goes on! It behoves us as a profession to give thoughtful consideration to the question how far we are responsible for these and kindred evils and to be particularly careful at the present time not to encourage them in the least degree by any mistakes on our part.

There is another aspect from which we need to be specially cautious and circumspect just now as to what we say and do, at any rate in this country. It is but too evident that our profession is being watched with suspicious and unfriendly eyes from more than one quarter, that our words and actions are being subjected to severe and hostile criticism, and that some of our most cherished and deeply-rooted doctrines and practices are being vigorously attacked by powerful individual and combined forces. Certain people seem to think it their duty and calling in life to take every opportunity to oppose whatever we try to do for the good of humanity and for the real advancement of medical science and art, and they are ever on the look-out for some malignant plot of medical Jesuitry. The fact must not be ignored that even within our own ranks there are men of ability and of high scientific and practical attainments who honestly and conscientiously differ from the vast majority of their brethren on important questions and whose actions are governed accordingly. We can only regret that such should be the case, but at the same time must treat them with consideration and respect. But what we have chiefly to contend against are the numerous and weighty outside influences

which combine together so far as lies in their power to bar all progress, to crush scientific investigation and research, and to wreck every measure which the medical profession as a body, with but few exceptions, demand as essential for the prevention and extermination of some of the most grave and terrible diseases which afflict the human race. Many of our most bitter opponents occupy high social positions and they may be, so far as I know, in their own spheres well-informed and clever people. They may even have acquired a smattering of physiology, or dabbled in medical works, and the vague and superficial knowledge they have thus obtained makes them conceited enough to imagine that they are thoroughly qualified to give a dogmatic opinion upon every conceivable subject relating to health and disease, as they are indeed quite prepared to take charge of the affairs of the world in general. But the great mass of opposition which we have to face consists in a combination, in various forms and degrees, of unreasoning prejudice, personal interests which brook no interference, sheer faddism or fanaticism, misguided sentiment, downright ignorance, and consummate impudence and conceit. When any of these obstructive forces are associated with power for active mischief, be it but that of a chairman of a board of guardians, the results are very likely to be most injurious or even disastrous to the cause of humanity. I repeat, therefore, that in face of these embarrassments we must be ever wary and careful as to our sayings and doings, avoiding everything that can rouse needless opposition or excessive friction, and giving no occasion for those whom we are compelled by their conduct to regard as our enemies to gain any advantage over us or to cast ridicule upon our claims.

In bringing this address to a close may I be permitted to refer briefly and comprehensively to what I conceive to be the real objects which such an authoritative and august gathering as an International Medical Congress should have in view and what practical purposes it is intended to serve? Surely it must never be regarded as a mere passing event which leaves behind no permanent impression or result. In general terms a congress of this nature may be described as intended to promote those aims which we as a profession individually and collectively always keep steadily before us, notwithstanding our differences of method and in spite of all opposition and difficulties, and by mutual instruction, help, and encouragement to render each one of us better fitted to carry out efficiently and intelligently the high functions and noble duties of our calling. And what are they? First and foremost comes the formidable task of diminishing mortality, of preserving and saving life, and prolonging its duration, so far as this purpose is consistent with the fitness of things. As a matter of fact, we instinctively do our utmost under every possible circumstance to avert death, and there is no more sad or trying ordeal for the practitioner of medicine to pass through than to see a young and promising life, or one in the full prime and vigour of manhood, engaged not uncommonly in active and useful work, and, alas, but too often the family "bread-winner," cut off by some dire disease which defies his best skill and most devoted efforts. Our surgical colleagues have a great advantage over us poor physicians in this matter and I frequently envy them when I think of the thrill of satisfaction and pleasure which the skilful operator must feel, especially at the present day, when he calls to mind the lives he has personally saved. But the mere addition of two or three years to the average duration of existence, or the prolongation of the life of one bowed down by the ravages of time or with constant pain and suffering, does not appeal to me as the supreme duty of the medical profession and I have no sympathy with some of the ideas now in vogue with regard to the attainment of longevity. I hold in my hand a summary of instructions as to how to live to be a hundred! I wonder who wants to spend a hundred years in this weary world, unless it be that conscience makes him afraid of venturing on the next! Other prominent objects which as a profession we are always striving to fulfil are the cure of particular diseases; their prevention, both among individuals and communities; and their extermination so far as this is practicable. Then I need but mention the wide field that is open before us and the constant call that is made upon our knowledge and skill in our attempts to relieve pain and suffering of every kind. But I venture to think that perhaps the most difficult problem with which we have to cope at the close of this nineteenth century, and one worthy of our supremest efforts, is how to deal with the mass of "morbidity" and "invalidism," the countless "ailments," real or imaginary, call them by what name you like, which crowd upon us on all hands and in every station of life, which render thousands upon thousands unequal to the ordinary avocations and duties of modern existence, which wreck the comfort and happiness of many a home, and which often become the starting point of pernicious habits that are sapping the very foundations of society in many directions, and if not checked must inevitably lead to widespread disaster.

What will be the ultimate practical outcome of the occasion which I have utilised as a text for my address cannot as yet be determined. We may reasonably hope that it has had some influence in creating a kindly and mutually considerate international feeling at a period in the world's history which is fraught with grave issues. Surely, moreover, it cannot fail to leave its mark upon the history of the progress of medicine and surgery and to promote in no small measure the all-important objects to which I have just referred. At the present moment we cannot shut our eyes to the disquieting fact that the relations between Russia and Great Britain are such as to cause serious anxiety with regard to the course of events even in the immediate future. We must all earnestly hope, however, that diplomatic statesmanship, aided by mutual consideration and a conciliatory spirit, may be able to guide us safely and successfully through all dangers and difficulties, so that "peace with honour" may continue between these two great empires. Their power for good upon vast masses of people, when acting in concert, it is impossible to over-estimate; while the beneficial results which may be anticipated from their combined efforts in the cause of civilisation and human progress are incalculable. On the other hand, the bare suggestion of war calls up scenes of horror, devastation, and desolation, with inevitable disastrous consequences to both nations, from which even the most hardened and thoughtless must instinctively shrink. Whatever may be the immediate and final results, international and professional, of this memorable cosmopolitan gathering, and whatever may happen in the future, I believe I am expressing the feelings and sentiments of my fellow-countrymen who were present and took part in its proceedings when I affirm that while time will dim more and more any passing impression of experiences not altogether agreeable which may have occurred to us as individuals until they are absolutely forgotten, there will always remain a vivid mental picture of novel, attractive, and interesting scenes, as well as of manifestations of kindly feeling and generous hospitality, and we shall one and all ever entertain a grateful and pleasant reminiscence of the Moscow Congress.

THE VIRUS OF VACCINIA AND ITS CULTIVATION.

BY A. F. STANLEY KENT, M.A. OXON.

THE identification and culture of the virus of vaccinia has for many years proved a problem of such difficulty as to baffle the endeavours of some of the most brilliant workers in bacteriology. Perhaps this is in some measure owing to the fact that the methods of bacteriology have been employed almost to the exclusion of histology, the idea that histological methods could afford any assistance having occurred apparently to very few. Nevertheless, that all experiments having for their starting point the collection of lymph from the vaccine vesicle would have to contend with the presence of multitudes of extraneous organisms will be evident to anyone who is conversant with the flora of the skin. It is indeed a matter of common knowledge that micrococci of various species—especially the staphylococcus pyogenes albus and staphylococcus pyogenes aureus—besides being present in large numbers on the surface and in the dead superficial cells of the stratum corneum, swarm in the openings of the hair follicles and even penetrate in them to a considerable depth.

It is for this reason that there arises so extreme a difficulty in sterilising the skin of patients about to undergo surgical operations, and when the object is to obtain lymph from vesicles in the skin itself and to obtain it free from extraneous organisms it is apparent that the task is one

calling for the exercise of the utmost care. All attempts to identify the virus by ordinary bacteriological means having failed I proposed to investigate the problem by somewhat different methods. It seemed probable that whatever organisms there might be in the vaccine lymph, at all events in the tissues around the vesicle, one might reasonably hope to find the specific virus in a state of comparative purity. Accordingly I undertook the preparation and examination of a large number of sections of the vaccine vesicle and its surrounding tissues. The preparations were made by vaccinating a susceptible animal in a suitable manner, excising the resulting vesicles at stages of their growth varying from a few hours after inoculation to their latest development, fixing and hardening these specimens by the best methods known to me, and, finally, after sectioning them, subjecting them to several different methods of staining. At the same time lymph was collected of different ages and examined bacteriologically. Some short account of the results obtained was communicated to the meeting of the British Medical Association at Bristol in 1894.

Of the extraneous organisms found it is necessary to say very little. Of course, upon the free surface of the sections, and especially in the openings of the hair follicles, there appeared crowds of micrococci. They were very obvious, occurred in clumps and masses of all sizes, and were as easily stained as is usually the case. They occupied not only the surface of the skin but extended also a considerable distance into the hair follicles, occurring as clumps of varying size and in the deeper parts as groups of two, three, or more. In the tissues immediately bordering on the breach of continuity in the skin small numbers of these organisms may sometimes be seen. In the deeper tissues, however—i.e., a short distance from the actual breach in the surface—they are conspicuous by their absence.

Whilst asserting the absence of the extraneous organisms I am far from denying the presence of other organisms in the tissues surrounding the vaccine vesicle—indeed, the exact contrary is the case—and I attach much importance to the fact, which I first pointed out in 1894, that there do exist organisms both in the vesicle and also in the surrounding tissues for a considerable distance from the site of the original lesion—organisms which in their morphological characters, their distribution in the tissues, their relation to cells, and their staining reactions are separated sharply off from the other organisms ordinarily associated with the processes of vaccinia. Morphologically they may be described as small—indeed, exceedingly minute—bacilli, about 1 micron in length and rather less than a half of this in thickness, with rounded ends, and usually occurring in pairs forming diplo-bacilli or dumb-bells. Photographs of these organisms were shown at the Bristol meeting of the British Medical Association in 1894. Morphologically, then, they appear to resemble the minute bacilli described by Klein, and independently by Copeman and myself, as occurring in early vaccine lymph, and I take it that the occurrence of these organisms also in the tissues under circumstances immediately to be described lends some probability to the view that they are fundamentally concerned in the causation of the disease. The distribution of these organisms in the tissues is a point of great importance. Unlike the extraneous organisms, they are not present in countless multitudes at the surface of the skin and in the hair follicles Indeed, as has been shown previously, they are absent from, or present in small numbers only in, lymph taken from vesicles after the fourth or fifth day from inoculation, whilst the extraneous organisms seem actually to increase in number as time goes on.

On the other hand, the bacillus, which for convenience it may be well to call simply "diplo-bacillus vaccinise," is present in the tissues surrounding the vaccine vesicle, not only soon after inoculation, but even up to the twelfth or fourteenth day and probably even later. It is of interest to note that it does not occur in the tissues as colonies or irregular masses, but is for the most part contained in cells. These cells appear often to be wandering cells; some, however, are of the nature of fixed corpuscles. As stated above the presence of these organisms in the tissues surrounding the vaccine vesicle may be recognised in specimens taken at all stages of the disease up to about the fourteenth day and the number does not seem to be materially lessened in preparations made at the later dates. Their presence is the more significant when it is remembered that they are present in what is practically a pure culture, for the extraneous organisms, though numerous on the surface, are absent from the deeper tissues affected by the diplo-bacillus vaccinise. The staining reactions of this bacillus are also of interest inasmuch as they afford some explanation of the extreme difficulty encountered in demonstrating its presence. For to stain the bacillus at all was found difficult and this difficulty has undoubtedly stood in the way of its earlier recognition. Most of the ordinary aniline dyes are unsatisfactory for the purpose and it was only by following out a somewhat complicated modification of Gram's method that I was able to stain it with certainty in the tissues. However, that the method is satisfactory is, I think, proved by the photographs which were shown at Bristol in 1894 and by preparations that were there exhibited.

I consider, then, that the morphological characters, the distribution in the tissues, the relation to cells and the staining reactions, together with the fact that cultures containing this organism produce in the calf and in children typical vaccine vesicles—vesicles which in their turn contain the same virus—sharply separate this diplo-bacillus off from the other so-called extraneous organisms and give support to the view that here at last we have before us the true germ of vaccinia. There are additional considerations which lead to the same conclusion. As will be remembered, a statement has been made that the peculiar minute bacilli described as occurring in early lymph are absent or nearly absent from lymph taken at a later date. In connexion with this it is significant that both Klein and I[1] have described in these organisms bodies which have the appearance of spores and have noticed the possible explanation by this circumstance of the permanence of vaccine lymph when preserved dry upon points. It is further to be noted that although the bacilli appear to be absent, or nearly absent, from mature lymph this is by no means the case with the tissues, the bacilli being recognisable in these until quite a late stage of the disease.

It is of course quite possible that the different conditions obtaining in the two situations are sufficient to determine on the one hand the formation of spores with subsequent or simultaneous breaking up of the bacilli and on the other a persistence of the ordinary form. Nevertheless, it appeared to me to be probable that in the case of lymph stored in contact with glycerine some development of the spores, supposing such to exist, might reasonably be looked for and this appeared the more probable from the fact, observed by many, of the great extent to which it is possible to dilute lymph with glycerine without injuring its power, and still more from the statement that lymph when so diluted and stored actually increases in virulence. I have accordingly examined a number of samples of glycerinated calf vaccine lymph and by the special methods of staining above alluded to I have been able to satisfy myself that whatever may be the case with late and mature lymph, in glycerinated lymph which has been kept for a few weeks the diplo-bacillus vaccinise is undoubtedly present. One explanation may, of course, be that in addition to the lymph itself a certain quantity of vesicle pulp would be used in the preparation of the glycerinated lymph and the bacilli may have come from this, but in most of the samples examined the solid material taken was reduced to a minimum and therefore this source of error was much lessened.

Another thing which tends to strengthen belief in the specific nature of the diplo-bacillus is the fact that, as briefly noted in a joint communication by Dr. Copeman and myself to the Bristol meeting of the British Medical Association in 1894 and more fully described by Dr. Copeman in the following year in London, a method was devised whereby it was found possible to cultivate an organism morphologically identical with the above and to produce by the inoculation of such cultures upon calves vesicles which very closely resembled those of ordinary vaccinia. And, further, I have shown that in vesicles produced by inoculation of cultures the same organism exists and has the same relative distribution as regards cells and extraneous organisms as I have described as characteristic of the diplo-bacillus vaccinise.

It was, however, very desirable that in addition to the cultures made in eggs other media of a more convenient character and capable of being solidified should be devised. I had already made very numerous experiments with all the ordinary culture media and with modifications of these without attaining any satisfactory result. Early in 1895, however, I was more fortunate and at the meeting of the British Medical Association held in London in that year I was able to report that some measure of success had been obtained.

[1] Brit. Med. Jour., Sept. 22nd, 1894.

My experiments were conducted upon the supposition that it should be possible to prepare some special mixture of albumen and glycerine so proportioned that whilst the former would afford nourishment and encourage the growth of the vaccine virus the latter would prevent the growth of extraneous organisms and so do away with the necessity of sterilisation by heat.

The following is a typical experiment copied from my notebook: "April 18th, 1895: Lymph was collected from the calf at the National Vaccine Establishment in Lamb's Conduit-street. It was inoculated upon a culture medium consisting of egg albumen with the addition of 10 per cent. of pure glycerine and incubated at 37° C." Five days after inoculation I have a note to the effect that there are many white colonies floating in the fluid, together with a growth which I compared with cotton wool. This cotton-wool-like growth I believe, for reasons which I shall presently set forth, to be the vegetative form of the diplo-bacillus vaccinise. At the same time that the above cultures were made I also inoculated with vaccine lymph tubes of the same culture medium which had been solidified by heat. The note here is that colonies, orange and yellow, are present. There was also upon the surface of the culture medium a thin film-like growth which I took to be the expression on the solid medium of the formation of the cotton-wool-like growth in the liquid. The coloured colonies consisted of staphylococci. Experiments were also carried out with media containing 15 per cent of glycerine, and in these the liquid tubes showed fewer of the white colonies but more luxuriant cotton-wool-like growth, and on the solid form the orange colonies were usually absent whilst the filmy growth was more pronounced. Finally, when the medium was made up with 20 per cent. or more of glycerine, the liquid tubes showed no colonies whilst the cotton-wool-like growth was well marked. These results were briefly alluded to at the meeting of the British Medical Association held in London in 1895.

On first observing the above-described cotton-wool-like appearance in the culture tubes I was of opinion that it represented a slow and incomplete coagulation or precipitation of a portion of the albumen contained in the medium, such precipitation being due probably partly to the action of the glycerine and partly to the dilution combined with the incubation at 37° C. As is well known, egg albumen is a complex mixture and contains several proteids which coagulate at different temperatures; moreover, the exact temperature at which coagulation takes place is determined by the concentration of the solution and the quantity of salts present. The coagulation temperature is generally given as from 70° to 73° C., but Gautier states[2] that coagula may also be obtained at 54° and 63°, whilst according to Corin and Berard,[3] by applying the method of fractional heat coagulation to filtered white of egg, coagula may be obtained at 57·5°, 67°, 72°, 76°, and 82°, the first two being due to globulins, the others to albumins. It seemed probable, then, that by mixing egg albumen with glycerine and subjecting it to incubation some amount of precipitation of proteid might be produced and this was rendered more likely by the experiments of W. Ramsden, who showed that by a prolonged action of heat a precipitation of albuminous fluids might be brought about at a temperature considerably below that generally assigned as specific for the body under consideration.

Accordingly I made numerous control experiments by mixing with egg albumen varying quantities of glycerine and submitting the resulting mixtures to similar conditions of incubation as obtained in the case of the culture tubes. Treated in this way it was found that in the case of tubes containing an addition of 33 per cent. of glycerine after a short time a certain amount of a woolly material appeared as clumps and cloudy patches in the fluid. It appeared, however, to consist of a definite solid substance suspended in a bright and transparent liquid and no general opalescence or cloudiness of the fluid was produced. In the case of cultures, on the other hand, the solid portion was much more finely divided and produced a definite opalescence in the liquid. Larger flakes of a peculiar semi-transparent character were also present, and at the upper edge of the fluid there was often observed a film-like portion of growth. In tubes containing a less proportionate amount of glycerine—viz., about 16 per cent.—and in which the albumen was about 33 per cent., a greater degree of opalescence was produced, but no increase in the cloudiness was observed to occur after the first few days, whilst in the case of similar tubes inoculated with vaccinia the opalescence was much greater, continued to increase and was accompanied by the formation of a flaky semi-transparent material, especially at the upper part of the tube where the fluid was in contact with air. In solid media it is of course less easy to make out the exact characters of the growth, in consequence of the physical condition of the nutrient material. It is, however, possible to ascertain that in its general characters the growth corresponds to the film-like material seen at the upper part of tubes containing liquid culture material.

Having thus succeeded in obtaining a growth in special culture media inoculated with vaccine lymph I next experimented with similar media inoculated with lymph which by admixture with glycerine and subsequent storage had been freed from extraneous organisms. These experiments gave results indistinguishable from those above described, with the exception that in no case did coloured colonies appear. Moreover, when cover glass preparations had been made and appropriately stained microscopical examination revealed in every case the presence of groups of organisms morphologically indistinguishable from that above described as diplo-bacillus vaccinise. Further, in the majority of the experiments they were the only organisms present, but in a few cases they were accompanied by extraneous germs. These cultures have been used for the inoculation of calves and have given results which tend to support the view of the specific nature of the bacillus.

It may perhaps be suggested that the finding of the organisms in the cultures is no proof of their multiplication in the artificial medium, since the individuals observed microscopically may have been some of those present in the original lymph used for establishing the culture. In answer to this objection I need only say that the cultures have been carried on from tube to tube and also the quantity of lymph used in the first inoculation was only $\frac{1}{100,000}$th of the quantity of fluid with which it was mixed. So that although in the tubes of the first generation cover-glass preparations might conceivably reveal the presence of an occasional bacillus, the occurrence of numerous groups would be most unlikely and would approach impossibility in the case of subsequent tube-generations had no multiplication taken place meanwhile. As mentioned previously, in a communication to the British Medical Association in 1894 it was stated that cultures of an organism morphologically indistinguishable from the above, but obtained from variolous crusts, when inoculated upon calves produced phenomena which up to the fourth day were similar to those produced by normal lymph, whilst in 1895 Dr. Copeman communicated to the association the further fact that by passing such cultures through two successive calves a lymph was obtained which produced typical vaccinia in a child. The cultures with which these results were obtained were fully described by Dr. Copeman in 1895. The medium used was the hen's egg, the yelk and white being well mixed together and subsequently inoculated with variolous material. Certain disadvantages were found to result from the use of such nutrient material. Transparency was lacking, subcultures failed, and isolation of special organisms by plate cultivations was not practicable. It was whilst endeavouring to improve upon these early attempts that I hit upon the plan of using the egg-white apart from the yelk and mixed with sufficient glycerine to inhibit the growth of extraneous organisms.

The result has been so far successful that I am now able to place the diplo-bacillus vaccinise under circumstances such that its multiplication is apparently possible, and to prepare cultures containing it in a pure state.

CROWNHILL (DEVONSHIRE) CONVALESCENT HOME.—The annual meeting of this institution was held on April 30th. The report showed that 265 patients had been admitted during 1897. The financial statement exhibited a balance in hand of £28 The report mentioned that the home, which is beautifully situated on the border of Dartmoor, is capable of accommodating 500 patients during the year, but the subscription list is not large enough to permit of this number being received.

NOTE ON THE SERUM REACTION OF MEDITERRANEAN FEVER AND ITS TREATMENT BY ANTITOXIC PLASMA.

BY A. R. ALDRIDGE, M.B., C M. EDIN., D.P.H.,
SURGEON-CAPTAIN, ARMY MEDICAL STAFF.

THE cases were all examined by the microscopic method. Some of them were also tested in the sedimentation tubes recommended by Professor Wright, but the larger quantity of blood and longer time required for this method seemed to make the former preferable. The blood was collected in capillary tubes, which were sealed and allowed to stand for 24 hours. The tube was then broken, the clot drawn out, and the serum transferred to a slide. In this way the serum obtained was not entirely free from blood corpuscles, but these did not appear to interfere in any way with the reaction. This serum was diluted with "loopfuls" of normal saline solution to the required amount, and a small quantity of a cultivation of the micrococcus Melitensis of Bruce mixed with it by means of a platinum loop. In all about 30 cases were examined, but, unfortunately, as the samples of blood were sent from various parts of the island of Malta, detailed notes were not kept of all.

TABLE I.—*Cases of Fever which showed the Reaction.*

No.	Day of disease.	Dilution of serum.	Reaction.	Remarks.
1	35th day.	1–10	Immediate; no reaction with Eberth's bacillus.	Died; ulceration of large intestine.
2	26th day.	1–10 1–25	Immediate.	Lasted 9 weeks; antitoxin.
3	3rd day. 8th day.	1–10 1–10	None. Immediate.	Antitoxin on 9th day; lasted 11 days.
4	4th day. 9th day.	1–10 1–10	None. In half an hour.	Antitoxin on 4th and 14th days; lasted 24 days.
	6th week.	1–10 1–100	Immediate. In half an hour.	Very severe constitutional symptoms; lasted over 3 months; antitoxin.
6	16th day.	1–10	Immediate.	Severe; with lung complications; lasted over 4 months; antitoxin.
7	10th week.	1–10	Immediate.	Prolonged; uncomplicated except with "rheumatic" pains.
8	3rd week.	1–10	Immediate; no reaction with Eberth's bacillus.	Resembled enteric fever at first.
9	5th week.	1–10	Immediate.	—
10	5th week.	1–10	Immediate.	—
11	9th day.	1–10	Immediate; no reaction with Eberth's bacillus.	Resembled enteric fever at first.
12	15th day.	1–10	—	—
13	12th week.	1–10 1–100	Almost immediate. None.	—
14	5th day.	1–10 1–100 1–500	Immediate. In half hour. None.	—

TABLE II.—*Cases of Slight Fever which did not show the Reaction.*

No.	Day of disease.	Dilution.	Reaction.	Remarks.
1	4th 13th	1—10 1—10	None. None.	Fever lasted 9 days; no relapse.
2	4th	1—10	None.	Fever lasted 6 days; no relapse.
3	8th	1—10	None.	Fever lasted 9 days; no relapse.
4	5th 7th	1—10 1—10	None. None.	Fever lasted 7 days; no relapse.

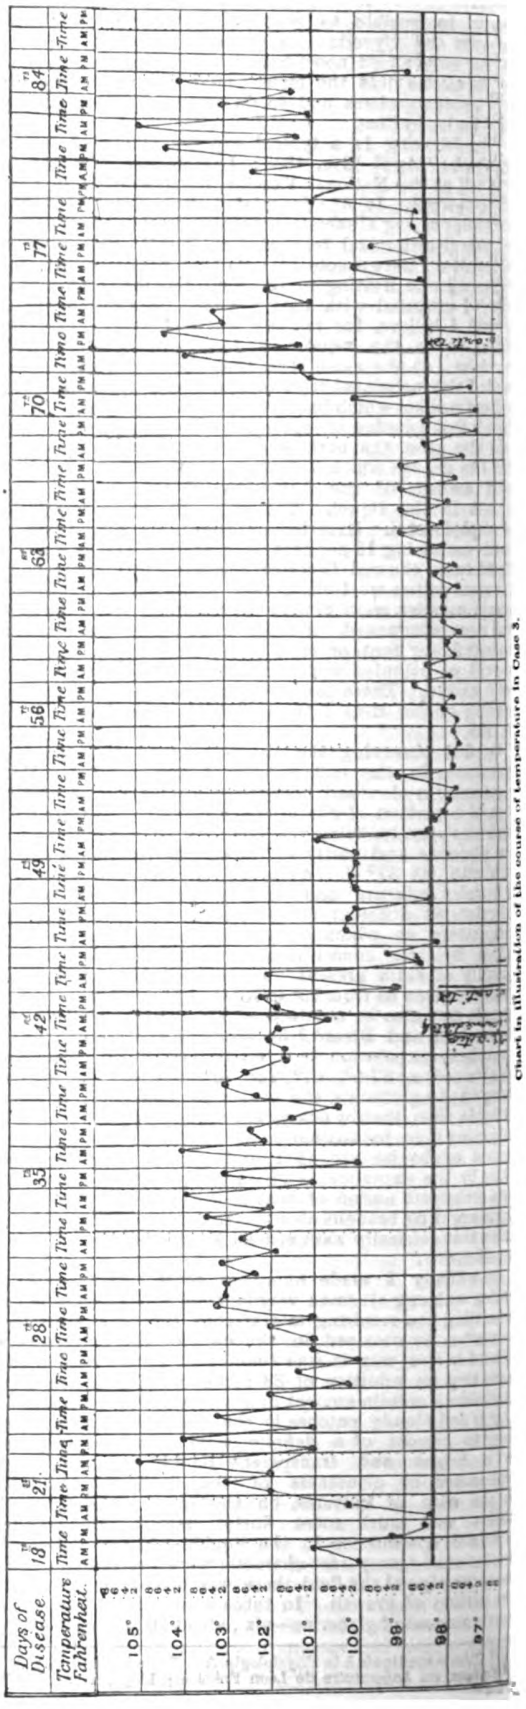

FIG. 1.

Chart in illustration of the course of temperature in Case 3.

In every case which could be considered clinically typical of Mediterranean fever a reaction was obtained. There remained a certain number of cases of uncomplicated fever lasting from six to ten days, not at all uncommon in Malta, which did not give the reaction at any time during their course or after the fever had subsided. Four cases of enteric fever were also tested with negative results, but gave a reaction with the bacillus typhosus. The course of the disease confirmed these results and in two of them post-mortem appearances also. Three cases during part of their course closely resembled enteric fever. Two of these were, in fact, so diagnosed at first, but no clumping was obtained with the bacillus typhosus, whereas the reaction with the micrococcus Melitensis was immediate, and in each case the after history left no doubt as to its nature; in two the usual relapses and "rheumatic" pains recurred for several weeks, and in the third a necropsy confirmed the diagnosis.

As regards the date at which the reaction first appears the number of cases examined during the first week has been very few. The fifth day was the earliest on which it was obtained and in no case which ultimately showed the reaction was it found absent after this. The cases were at first all tested with a dilution of 1–10 and the reaction in almost every case occurred immediately—that is, the micrococci were found clumped when the slide was put under the microscope, though a few could often be seen free; in from a quarter to half an hour these, too, were clumped. The reaction was also well marked in greater dilutions up to 1–100, though with such a rather longer time was generally required up to half an hour. If a considerable quantity of the micrococci be added in putting up the specimen the clumping can be recognised with the naked eye.

Five cases were treated with the antitoxic plasma prepared by Professor Wright of Netley. Of these 2 cases which were in their sixth and ninth week of disease did not appear to be affected in any way by the injection. The third case was a very severe one with great prostration, in which the fever had lasted seven weeks with only one partial remission; 30 c.c. of the antitoxin were injected and a marked improvement commenced from the following day. The tongue, which had been dry and brown, and the breath, which had been very fœtid, improved very markedly; the collapse became less, and the temperature came down and remained normal from the eighth day after the injection (see Fig. 1). Another relapse occurred after three weeks and the temperature again decreased three days after another injection of 15 c.c. of the antitoxin, but this improvement was not maintained and no more of the antitoxin was available.

The two other cases were recent ones and uncomplicated. In Case 4 30 c.c. of antitoxin were injected on the fifth day. The temperature, which had reached 106°, gradually fell till it ranged between normal and 101°; but on the fourteenth day, as it showed a tendency to rise again, another similar dose was given and was followed again by a fall of temperature,

FIG. 2.

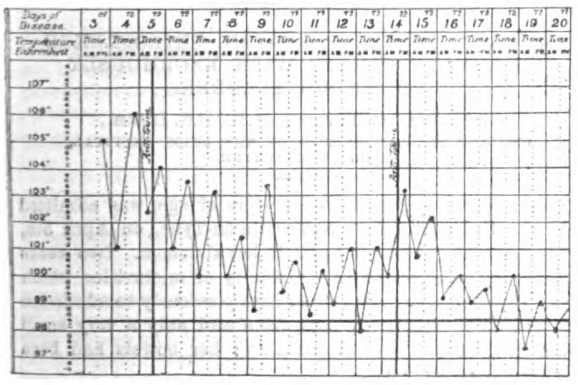

Chart in illustration of the course of temperature in Case 4. After the twentieth day the temperature remained practically normal.

which did not rise above 100° from the third day afterwards (see Fig. 2). This case did not show the serum reaction on the fourth day, but did so on the ninth, which, however, was after the first injection of antitoxin.

In Case 5 no serum reaction showed on the fourth day, but it did so on the eighth day. On the ninth day 30 c.c. of antitoxin were injected and the temperature, which had already shown a tendency to come down but continued between 100° and 102°, reached and remained normal from the third day after the injection.

The recorded temperatures in Case 5 were as follows, two observations being taken each day, the first in the morning and the second in the evening:—Third day of the disease, 105·0° F. and 101·0°; fourth, 103·0° and 103·0°; fifth, 102·4° and 103·0°; sixth, 101·4° and 102·4°; seventh, 100·4° and 102·2°; eighth, 100·2° and 102·0°; ninth, 100·0° and 102·6° (antitoxin was injected); tenth, 100·0° and 101·2°; eleventh, 100·4° and 99·4°; twelfth, 98·4° and 99·0°; thirteenth, 98·2° and 99·0°; fourteenth, 98·0° and 97·6°; fifteenth, 97·8° and 98·4; and sixteenth, 97·6° and 98·4°.

In coming to any conclusion as to the benefit resulting from the antitoxic serum a great difficulty lies in the fact that whereas from analogy with the use of similar serums in diphtheria and tetanus and also experimental inoculations the best results are to be expected in recent cases, yet diagnosis during the first week is very difficult, for besides enteric and other causes of fever there is a form of slight fever, already referred to, common in Malta. This lasts from about six to ten days and is apparently different from Mediterranean fever but only distinguishable from it by its short duration and by the serum test. Now this test does not seem to occur until the end of the first week and is itself of no value after the injection of antitoxin, which presumably will produce the reaction in the blood.

The cultivations used in these experiments were from Dr. T. Zammit's laboratory, with whose assistance much of the work was carried out.

Malta.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF DEPRESSED FRACTURE OF THE SKULL.

BY CLAYTON A. LANE, M.D. LOND.,
SURGEON-LIEUTENANT, INDIAN MEDICAL SERVICE.

ABOUT noon on Aug. 17th, 1897, while the 18th Bengal Lancers were encamped at Kushalgarh on their way to Kohat, a sowar was kicked on the head by his horse and was brought to the hospital tent. He was insensible, answering no questions. His pulse was irregular and very easily compressible; his pupils were neither contracted nor dilated and were equal. Crossing the centre of the left eyebrow and running upwards and inwards for an inch was a wound leading down to the periosteum. Above and inside the upper end of this wound a depression could be seen and felt through the skin and on putting a finger into the wound a fracture was felt starting near the middle of the upper edge of the orbit and curving upwards and finally outwards across the temporal ridge, where it was lost. The curve had a radius of about an inch and the portion of bone in its concavity was depressed, the greatest depression being along the line of fracture, where it amounted to ¼ in. The man's condition seemed to me to be so critical as not to justify my waiting to operate till water could be boiled and cooled, though the water I should have to use came from a dirty tank near the camp. Accordingly I began the operation at once, using carbolised water (1 in 40) for lotion and using the instruments provided in the field surgical pannier. On starting to enlarge the wound upwards the patient began to struggle, so the hospital assistant gave him chloroform. After trephining and inserting the elevator the depressed bone sprang at once into position and remained there. The bleeding vessels were twisted, not tied, and the skin was sewn up with silver wire without any drain. During the operation he stopped breathing, the pulse being still felt at the wrist, but after artificial respiration had been continued for some minutes he began to breathe again. With the thermometer at over 100° F. in the shade the cessation of artificial respiration was an even greater pleasure than usual. 20 minims of spirit of ether were injected after

the operation and he shortly revived. In the evening his temperature was normal and his pulse was 100. The patient was sensible and had no pain.

The question of after-treatment was a most anxious one as the regiment was to march next day, but after grave consideration I determined to have the patient carried with us on the two marches to Kohat, 30 miles in all, for at that time the chances of his obtaining efficient medical aid at Kushalgarh were more than remote. He was carried in a doolie by Kahars, starting at 4.30 A.M. each day and getting into camp before the heat from the sun was great. On the evening of Aug. 18th his temperature was 100° F. but the wound looked perfectly healthy. On the 19th his temperature was normal and he was quite free from any pain. I left him at Kohat and subsequently heard from Surgeon-Captain Bamfield that he never had a bad symptom. He rejoined the regiment about six weeks later. In February last, six months after the operation, the patient told me that he had been quite well since he rejoined the regiment and had had no headache. He had been doing his duty satisfactorily and had not been ailing in any way. There was a slight scar 1½ in. in length above his left eyebrow and on the site of the fracture was a prominence giving the impression that the previously depressed bone had been too much elevated. Where the bit of bone had been removed there was a slight depression and its area, too, was small.

The fact that the wound remained aseptic was probably due to the following reasons, at least in part. So far as the water went either the carbolic acid was effectual in sterilising it sufficiently to enable the leucocytes to do their work easily or the micro-organisms it must have contained were not pathogenic, or if they were so they were not educated to virulence. The silk supplied in the field equipment is not kept in an antiseptic solution and cannot be kept surgically clean, and I do not believe that silk can be sterilised by a few minutes' soaking in carbolic solution. I accordingly avoided it, twisting all vessels. Before using the silver wire for suturing I rubbed it thoroughly with a clean cloth, hoping that in this way I might be able to get it almost surgically clean, just as one can clean the outside of a catheter. The measures used to cleanse it were probably effectual for no stitch-abscess resulted.

The case seems to show with particular force the well-known fact that when in the field and away from a contaminated hospital building (as all hospital buildings tend to become) operations can be successfully performed without all the precautions necessary in a fixed hospital; and though that, of course, is no cause for not taking every precaution which can be taken, still it shows that under these circumstances the risk of septic infection is less than it appears to be, and that it is justifiable, if not an actual duty, to make an attempt to save life even though the surroundings may appear far from favourable.

. Jullunder.

RUPTURE OF GALL-BLADDER; LAPAROTOMY TWENTY-FOUR DAYS AFTER INJURY; RECOVERY.

BY J. M. H. MARTIN, M.D. VICT., F.R.C.S. ENG.,
SENIOR HONORARY SURGEON TO THE BLACKBURN AND EAST LANCASHIRE INFIRMARY.

IN THE LANCET of March 12th, 1898, Mr. Whipple records a case of cyst in connexion with the liver apparently due to the rupture of a hepatic duct. In the following case the bile escaped into the peritoneal cavity from a ruptured gall-bladder. Such an injury is generally considered fatal, but, as this case shows, not necessarily so.

A boy, aged nine years, was admitted to the Blackburn and East Lancashire Infirmary on Nov. 26th, 1897. Four days before admission his abdomen had been run over by a cart weighing 15 cwt. After the injury he was carried, or rather dragged, a quarter of a mile to his home. The medical man who then saw him reported that "he was suffering from shock and pain in the right side of the belly not specially confined to the liver." Next day his symptoms were distinct abdominal swelling, slight discolouration over the region of the gall-bladder, and a temperature of 101° F.; there was no vomiting. On the 24th there was retention of urine and his "bowels were moved, the motion giving marked evidence of blood." On admission to the infirmary the boy looked very ill and complained of pain in the abdomen, which was slightly distended but not very tender to the touch. Nothing else was made out by physical examination of the abdomen. His pulse was 100 and his temperature was 98°. His tongue was furred; there was no sickness. Nothing in the way of local treatment seemed indicated and milk with lime-water was the only food given. At 10 P.M. the temperature rose to 101·8°. Once during the afternoon there was vomiting of curdled milk. Next morning the abdominal tenderness had almost disappeared and the boy looked much better. He complained of being hungry. From this time till Dec. 2nd (six days), when he was sent home, improvement was very rapid; in fact, two days before discharge he was found running about the ward during the nurse's absence for a short time. He was discharged as being "well" and was taken home to Accrington by an uncle who carried him most of the way. The uncle states that in the train the boy complained of feeling ill and when he was seen the same evening by his former medical attendant he was "complaining of pain in the abdomen and vomiting bilious fluid." The abdomen had become distended again. He remained at home for twenty-one days and during this time the stools were clay-coloured. He was sick occasionally during this time and the abdomen remained swollen. On admission to the infirmary for the second time a great change was evident in the boy. He had lost a great deal of flesh; the abdomen was full of fluid of some kind but was not tender. The temperature was 98° and the pulse was 110. The tongue was furred; there was no jaundice, neither was bile present in the urine; the stools were clay-coloured. The temperature remained normal during the second twenty-four hours after admission. On the third day the abdomen was opened in the middle line above the umbilicus by an incision 2 in. long. Nearly five pints of fluid escaped. This fluid, which was deeply bile-stained, was in the general peritoneal cavity and not in any way limited by adhesions. The coils of intestine in the neighbourhood of the liver were matted together with lymph. The gall-bladder was empty and was thought on digital exploration to be adherent to the parietal peritoneum. A drainage-tube was left in the wound and a bulky dressing was applied. The boy bore the operation well and there was no rise of temperature afterwards. The dressing was removed on the second day and found to be soaked with bile-stained fluid. The boy's general condition had improved, his tongue being moist and his pulse better. The after-history is only remarkable for the rapidity of recovery. The temperature never reached 100°, the discharge became less each day, and the tube was discontinued on the seventh day. The total quantity of fluid absorbed by the dressing would almost equal the first amount removed. Bile was noticed for the first time in the fæces on the third day after the operation. The urine was examined each day for bile but it was never detected. The daily average quantity of urine was only 20 oz. The patient was discharged on Jan. 1st, 1898, and when seen on March 21st was quite well.

Blackburn.

A CASE OF INCARCERATED RETROFLEXED PREGNANT UTERUS WITH ENORMOUSLY DISTENDED BLADDER.

BY WILLIAM SIMPSON, M.B., B.S. DURH.,
RESIDENT MEDICAL OFFICER OF THE UNION HOSPITAL, NEWCASTLE-ON-TYNE.

A SINGLE woman, thirty-two years of age, was admitted into the Union Hospital, Newcastle-on-Tyne, on April 5th, 1898, complaining of great pain in her abdomen. Two weeks previously she began to have difficulty of micturition which gradually increased. For three days previously to admission she had been unable to pass urine and only a very small quantity had escaped involuntarily; her bowels had been confined since April 1st.

On examination the abdomen was very much distended and tense and a swelling, which was dull on percussion and on first consideration appeared like a large ovarian cyst, extended from the pubes to 2 in. above the umbilicus. Both legs and the vulva were œdematous. On vaginal examination the fundus of the uterus was felt to be enlarged; it occupied Douglas's pouch and the cervix was felt to be

directed forwards above the pubes. The patient said that she had not menstruated for the last three months. A soft rubber catheter was passed into the bladder and 196 oz. of foul-smelling, high-coloured urine were drawn off, the last few ounces of which were loaded with pus. In addition fully 4 oz. escaped during examination. No effort was made to replace the uterus that day on account of the collapsed state of the patient. On April 6th she passed 43 oz. of urine naturally, 77 oz. were drawn off by the catheter, and on vaginal examination the uterus was found to have righted itself. On the 7th 72 oz. of urine were passed naturally and 14 oz. by the catheter, after which she was able to empty her bladder voluntarily and the quantities passed on the three succeeding days were 70 oz., 80 oz., and 60 oz. respectively. She was discharged on April 20th in good health, the fundus of the uterus extending to 2 in. below the umbilicus. The œdema of the legs and vulva had completely disappeared.

The quantities of urine above stated are strictly accurate, they having been measured under my personal supervision. I should like to know what has been the largest quantity of urine known to have been drawn off from the female bladder.

I am indebted to Mr. Dodd, visiting surgeon to the hospital, for permission to publish this case.

Newcastle-on-Tyne.

NOTE OF A CASE OF LIPOMA OF THE HAND.

BY ARCHIBALD CUFF, B.A., B.C. CANTAB., F.R.C.S. ENG.

THE presence of a fatty tumour in the palm of the hand, though more frequently met with there than in the sole of the foot, is of uncommon occurrence. The following case was recently under my care in the Sheffield Royal Infirmary.

The patient, a woman, aged forty-four years, had had the tumour, which had slowly increased in size, for eight years. The inconveniences caused by its position and size rather than any feeling of discomfort were her reasons for having it removed. The tumour occupied the position of the thenar eminence, reaching above to the level of the base of the first metacarpal and below projecting between the thumb and index finger. From the dorsum of the hand it was seen to project between the heads of the thumb and index metacarpal bones, pushing them apart. Irregular and lobulated in outline, the mass gave an indefinite sense of fluctuation on palpation. Its position not lying in the direct course of the tendon sheath, the way in which it was inserting itself between the metacarpal bones, and, lastly, the negative result on pushing an exploring needle into the mass, distinguished it from a cyst in connexion with the tendons, with which these tumours are most likely to be confounded. It was removed by an incision made over its long axis through which it shelled out easily. It then appeared to be of greater size than was suspected before operation, several lobules being situated beneath the palmar fascia extending to about the mid line. Very little bleeding was met with and it was noticeable after removal of the tumour that there was no fatty connective tissue to be seen in the wound. I am indebted to Mr. Shaw, surgeon to this institution, for permission to treat and record this case.

Sheffield.

THE ROYAL INSTITUTION.—On Friday evening, May 13th, Professor Tilden delivered an address the title of which was "Recent Experiments on Certain of the Chemical Elements in Relation to Heat." After a brief sketch of the investigations of specific heat made by the earlier observers—such as Dulong, Petit, Regnault, and others—he said that the discrepancies in the results obtained were probably due to the metals examined not being in a state of purity, and that Dulong and Petit's law, according to which the product of the atomic weight and specific heat of an element is a constant number, is only approximately true. Experiments were shown with fusible metal, fusing and welding of platinum foil, galvanically deposited antimony, soluble and insoluble chromium chloride, &c., and also with Professor Joly's differential steam calorimeter. In the library Mr. Goold of Nottingham showed the production of rapid circular motion of tassels and paper discs by means of vibrating steel bars.

LONDON HOSPITAL.

A CASE OF PARTIAL RETROFLEXION OF THE GRAVID UTERUS PERSISTING TILL THE END OF THE EIGHTH MONTH; SPONTANEOUS DELIVERY.

(Under the care of Dr. G. E. HERMAN.)

THE rarity of the condition present in the following case is very great and the value of the record is enhanced by Dr. Herman's remarks. For the notes of the case we are indebted to Dr. H. M. Rigby, resident accoucheur, and Mr. J. F. Walker, clinical clerk.

A woman, aged twenty-seven years, was on Feb. 28th, 1898, admitted into the London Hospital under the care of Dr. Herman. The patient had had no previous illness. She had menstruated regularly and without pain from the age of fourteen years until the last week in June, 1897. She was married in March, 1897. She saw nothing after the last week in June, 1897. In the second week of November she found that she could not pass urine. She sent for a medical man, who relieved her with a catheter. A week later she was again unable to empty the bladder and it was emptied with a catheter. In the following week she again had retention of urine. The medical man passed a catheter as before, but on no occasion did he make any further examination than what was necessary for the passage of the catheter. From this time until Feb. 22nd, 1898, she had no further trouble, but then she began to have pains which she took to be those of labour. She sent for Dr. H. Richardson, who found the condition which will be described. She was removed to the London Hospital in order that her condition might be more thoroughly investigated.

On admission to the hospital the abdomen was found to contain a swelling, mainly to the right of the middle line, which reached to the lower ribs. The fœtal heart was heard over it, most loudly at about the level of the umbilicus. The girth at the umbilicus was 35 in.; midway between the umbilicus and the pubes it was also 35 in. The distance from the umbilicus to the right anterior superior iliac spine was 8 in., to the left anterior superior iliac spine 7½ in., to the pubes 7 in., and to the ensiform cartilage 6½ in. The measurement between the internal borders of the anterior superior iliac spines was 9¾ in., between the iliac crests it was 11¾ in., and the external conjugate diameter was 7½ in. By the vagina there was felt a firm, rounded swelling which filled the hollow of the sacrum and which was covered in front by the posterior vaginal wall. There was room enough to allow the finger to pass between this swelling and the pubes. The vagina ran directly upwards behind the symphysis, but the finger could not reach the top of it. No os uteri could be felt.

After admission the patient was anæsthetised and examined. It was made certain that the os uteri was not within reach of the finger. The whole hand was then inserted into the vagina; and when this had been done the os was felt to the right and so high up that it could not be reached without the introduction of the whole hand. The os uteri was large enough to admit a finger, but not larger. After the examination under anæsthesia the patient had no labour pains and no trouble with micturition until the evening of March 3rd. She then began to have slight pains in the lower abdomen and back, and amniotic fluid commenced to run away. On the 7th a digital vaginal examination was made and the condition was found to be the same as it was before. The os uteri was quite out of reach of the finger. The pains continued. On the 9th a digital vaginal examination was again made. The state of things was the same, the os uteri being

still out of reach. Some meconium came away. During the night and the following morning the pains increased in severity and frequency, and at 3.15 P.M., during the absence of the resident accoucheur, the breech of the child was expelled without resistance. The legs were extended. There was delay in the delivery of the head, which had to be manually extracted. The child was born dead. The mother recovered without any unfavourable symptom.

Remarks by Dr. HERMAN.—The above case is published because such cases are rare and those showing that the delivery may safely be left to nature are still rarer. G. Veit[1] collected 11 such cases and Depaul[2] has recorded two others. These are all that I have found. The majority of the patients, as in the above instance, were primiparæ and, also as in the above case, most of the labours came on prematurely. In most of them some interference was thought to be necessary; either the body of the uterus was pushed up or the cervix was pulled down, as in Oldham's case. These manœuvres were probably harmless but unnecessary. Michaelis manually dilated the cervix, and Depaul in one of his cases incised the os uteri so that he might manually deliver. In his other case Depaul incised the uterus through the posterior vaginal wall, with the result that the patient died. The only cases which have been left to nature have been under the care of English physicians—viz., those of Merriman,[3] Ramsbotham,[4] and the one above reported. In each of them delivery took place, the displacement of the uterus having no more serious effect upon the labour than to somewhat prolong it.

The most difficult clinical question in these cases is the diagnosis between pregnancy in a uterus misshapen in this unusual way and (1) extra-uterine pregnancy under the peritoneum behind the uterus, a condition which is probably more common than the former. It was to decide this question that the patient was admitted into the hospital. The diagnosis is made by finding or not finding the uterine body in front of, and distinct from, the fœtus-containing cavity. In this case the difficulty was to find the os uteri; when this was done it was found that the os led into the cavity which contained the fœtus and there was no uterine body distinct from the main swelling. 2. Very similar physical signs to those in this case may be given by a fibroid in the posterior wall of the uterus occupying the hollow of the sacrum, with pregnancy in the uterine cavity above the fibroid. I have published such a case in which I performed Cæsarean section.[5] The complication of pregnancy with a fibroid in the true pelvis of about the same size as the head or breech of a fœtus is very unlikely to happen. The only criterion I can point out is the great elevation of the os uteri in persistent retroflexion of the uterus. Were a pregnant uterus so pushed up by a fibroid that its os came to lie as high as in the case now reported, the difference in hardness between the fibroid and the cavity containing the liquor amnii would be easily appreciable by abdominal examination, for such a fibroid would reach high above the true pelvis. 3. An ovarian tumour in the true pelvis ought not to cause much difficulty in diagnosis, for in this case a sulcus between the tumour and the pregnant uterus would be palpable.

BEDFORD GENERAL INFIRMARY.

A CASE OF FRACTURE OF THE BASE OF THE SKULL; NECROPSY.

(Under the care of Mr. COLBY SHARPIN.)

FRACTURES of the skull are always of interest and many problems connected with them are still unsolved. The mechanism of the production of many forms of these fractures is by no means clear. A valuable paper by Chipault and Braquehave was contributed to the *Archives Générales de Médecine* of Paris in September, 1895; it deals with the question of the mechanism by which fractures of the skull are produced.

The patient in this case was a man, aged eighty-one years, who, while he was crossing a road in Bedford, was knocked down by a cart which was going at the rate of seven or eight miles per hour. He was brought into the infirmary at 8.30 P.M. on April 9th. On admission he was comatose. Upon examining him a scalp wound 2 in. in length was discovered over the left of the occipital bone. There was also a linear fracture in the occipital bone, but no displacement had occurred. Over the left side of the frontal bone there was a small incised wound ¼ in. in length which was superficial. There was profuse hæmorrhage from the left auditory meatus which lasted for several hours. Dr. Ross diagnosed a fracture of the middle fossa of the base of the skull. The patient remained comatose until the time of his death, which took place at 7.30 A.M. the following day.

Necropsy.—At the post-mortem examination, which was made on April 11th, all the internal organs were found to be healthy except that there were pleuritic adhesions on the right side of the chest. The heart was full of blood, especially the right auricle and ventricle. Upon opening the skull the frontal lobes of the brain were seen to be encased in blood-clot. The base of the brain was also covered with blood-clot. There was no laceration of the cerebral substance. When the brain was removed the base of the skull was found to be covered with blood-clot, fluid blood, and serum; after clearing this away Dr. Ross discovered a fracture which extended from the linear occipital fracture before mentioned to ¼ in. beyond the petrous portion of the temporal bone. The tearing through of the superior and inferior petrosal sinuses and the left occipital and the left lateral sinuses explained the profuse hæmorrhage which occurred.

Remarks by Dr. ROSS.—With regard to the different ways in which this lesion may be caused I have seen the following various types: (1) a man falling 20 ft. from a scaffolding and alighting upon his feet fractured the middle fossa of the base of his skull; (2) a "coupler" caught by a buffer on the left side of his forehead fell backwards upon the "sleepers" fracturing the anterior fossa of the base of the skull; (3) a youth, aged sixteen years, when diving into a swimming bath struck the top of his head, sustaining a fracture of the middle fossa of the base of the skull; and (4) in the case under consideration the patient's left occipital bone was caught by the right shoulder of the pony and he being precipitated forward upon his forehead the posterior and middle fossæ of his skull were fractured. If a linear fracture be found at the point of impact and there be signs of one or other of the fossæ of the base of the skull being injured it is tolerably certain that post-mortem examination will show the vertical and basal line of fracture to be continuous.

BRADFORD ROYAL INFIRMARY.

A CASE OF ATRESIA ANI VAGINALIS.

(Under the care of Mr. W. HORROCKS.)

THE following very interesting example of a by no means common condition demonstrates forcibly the great value of Rizzoli's operation of transplantation of the anus. The name of "anus vulvovaginalis" has been applied to this variety of irregularity in development and up to the present, according to Freeman, more than sixty cases have been recorded.[1] It is rarely seen in the adult, but Dwight[2] met with an instance of it in a woman aged thirty-two years.

An infant, aged six months, was admitted into the Bradford Royal Infirmary on Jan. 26th, 1895. The patient, who was the ninth child of healthy parents, suffered from malformation of the anus. All the other children were well formed and no similar deformity was known to exist on either the father's or the mother's side. The mother was in good health while carrying the child, who was born at full term after an ordinary labour. Shortly after birth there was some difficulty in relieving the bowels and this increased as the child grew older. On admission the child was found to be well nourished and except for the malformation of the anus well developed. In the ordinary position of the anus there was no depression, but there was an elevated and discoloured tag of skin, from which a raised blue raphé reached forwards to the vaginal orifice. At the posterior commissure of the vagina was the termination of the bowel which looked directly forwards. The external genitals were otherwise well formed. On passing a probe into the rectum it travelled backwards for about half an inch and then

[1] Philadelphia Medical News, Sept. 21st, 1895.
[2] American Journal of the Medical Sciences, April, 1895.

passed in an upward direction. The probe could be easily felt through the skin when it was lying in the rectum. On Jan. 28th, the child having been anæsthetised, an incision was made encircling the anus and this incision was prolonged backwards to the tip of the coccyx. The bowel was thus freed from the surrounding tissues. It was closely adherent to the skin behind the orifice and in separating it the gut was opened, but the orifice was closed by a catgut suture. The bowel was now freed in front, care being taken to spare as far as was possible the tissues around the anal orifice. The anus was now brought backwards and fixed about an inch in front of the coccyx by deep and superficial catgut sutures. The perineum was formed in front of the anus and the aperture in the vagina was closed with catgut sutures. There was no difficulty in bringing together the two sides to form a firm perineum. The child was somewhat collapsed after the operation. The wound healed well at the back part, but there was some suppuration about the perineum which ultimately healed by granulation. The child was discharged from the infirmary a fortnight after the operation and has since done well, there being no incontinence of fæces and no obstruction at the orifice.

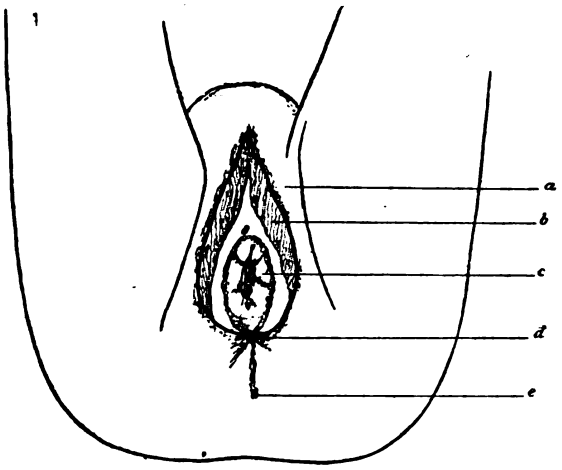

Diagram showing position of anus. *a*, Fold of labium majus separated to expose parts. *b*, Labium minus. *c*, Hymen, showing opening of vagina. *d*, Anus placed at posterior commissure of vagina. *e*, Fold of skin showing position of normal anus.

Remarks by Mr. HORROCKS.—The above case is interesting as being an example of a somewhat rare malformation of the anus. The termination of the gut opened into the cloaca, the recto-vaginal septum being imperfectly developed. The forward bend of the rectum before its final twist backwards is an indication of this condition in a normal state. The close proximity of the bowel to the skin and the tight adhesions between them may account for the rectum not being drawn upwards during development and the non-formation of the recto-vaginal septum. The elevated raphé with the rudimentary tag at the natural position of the anus shows the imperfect closure of the two halves. In a similar case which was treated some years ago a bent director was passed into the rectum and an opening was made in front of the coccyx. The margins of the communication with the vagina were then freshened and brought together with stitches. The new opening was kept open with a piece of catheter. In this case the anus was constantly contracting and frequently required dilatation, and the infant died about six months after the operation from whooping-cough. Shortly before treating the present case a description of Rizzoli's operation was seen in Ball's "Diseases of the Rectum" and the operation seemed to be suitable for the case. There was some doubt as to whether the dissection of the sphincter ani would destroy its nerve-supply and to avoid this the tissues around the anus were spared as much as was possible. The greatest difficulty of the operation was the separation of the skin from the rectum behind the anus, the parts being firmly adherent. The formation of a solid perineum seems the great advantage of Rizzoli's operation. The present case is most interesting from the fact that the sphincter is now efficient and obstruction of the bowels, which was a prominent symptom before the operation, no longer troubles the child.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Intestinal Obstruction from Thickening of the Great Omentum.—Sarcoma of the Kidney.—Presence of Fat in the Glanders Bacillus.—Intra-spinal Tumour.—Thickening of Subcutaneous Veins.—Exhibition of Specimens.

A MEETING of this society was held on May 17th, the President, Dr. J. F. PAYNE, being in the chair.

Dr. T. A. BOWES and Mr. CHARLES POWELL WHITE showed a specimen of Intestinal Obstruction due to Induration of the Great Omentum. The patient was a man, aged sixty-six years, who was treated in the Herne Bay Infirmar for tertiary syphilis and developed signs of increasing intestinal obstruction, from which he died. The great omentum was found to be much indurated and contracted, so that the lumen of the colon for a length of six inches was reduced to the size of a penholder. There was no sign of malignant disease and the condition was regarded as syphilitic.

Mr. CHARLES POWELL WHITE showed a specimen of Sarcoma of the Pelvis of the Kidney. The patient was a girl, aged six years. She had suffered from ascites for six months but had never had any renal symptoms. The kidney was not enlarged. There was a diffuse growth situated between the mucous membrane of the pelvis and the pyramids, red in colour and firm in texture. It extended beyond the hilum to the retro-peritoneal tissues about the ureter. There were secondary deposits along the whole length of the intestines and in the pancreas. Microscopically the growth consisted of round cells with well-marked nuclei in a delicate network of interlacing fibrils, in which were some branched cells.

Mr. S. G. SHATTOCK read a paper on the Presence of Fat in the Glanders Bacillus. He had been led to inquire whether the bacillus contained fat from the luminosity of the flame having often struck him whilst sterilising the loop in carrying on cultures. The method adopted was to transfer superficial portions of potato cultures to cover glasses, mix them with distilled water, and expose the material in dark chambers to the prolonged action of osmic acid vapour; examinations of the material (still moist) were made by means of the hanging drop. Careful microscopic study revealed the presence of minute points of fat, coloured deep black, in the longer forms of the bacilli. Such points were limited to the longer forms which occurred especially in potato cultures; they did not correspond either in size or number with the clear, oval, or spherical unstained areas seen in preparations dyed with carbol fuchsin; these Mr. Shattock regarded as vacuoles similar to those in the cholera spirillum. Such spherical vacuoles had, again, to be distinguished from the segmentation of the protoplasm often presented by this bacillus. The presence of fat in yeast had been long known. Brieger's analysis of Friedländer's pneumococcus had shown the presence of fat moreover in this, whilst Koch had demonstrated the same class of substance in the tubercle and Unna in the lepra bacillus. A fatty acid was elaborated again by the diphtheria bacillus. The fat, however, lay in some of these cases without or around the bacterial cells. Whether the presence of fat in the glanders bacillus was physiological or a mark of degeneration was disputable. Mr. Shattock exhibited also a series of White Mice infected with pure cultures of the glanders bacillus by subcutaneous injection. Death occurred in from two to three weeks. The chief organ affected was the spleen, which was greatly enlarged and studded with glanderous nodules in which microscopic examination showed the bacilli in an unmixed condition; the testicles were uninvolved. It was invariably stated in textbooks that white mice were immune from glanders. The disease ran a somewhat chronic course, for in the field mouse death took place in from two to eight days. The insusceptibility, in short, was relative, not absolute, in this case.

Dr. MORLEY FLETCHER exhibited a specimen of an Intra-spinal Tumour from a man, aged fifty-five years, who was under the care of Dr. Gee at St. Bartholomew's Hospital. The total duration of symptoms was sixteen months. The chief symptoms were loss of power and pains in both legs. There were no pains in the back and a striking feature in the clinical history was the very sudden termination of the case with symptoms of collapse. The growth was an oval

tumour in the lumbar enlargement arising within the posterior part of the cord near the central canal. It was a glio-sarcoma. It was pointed out that intraspinal malignant tumours were extremely rare, especially sarcomata, and that few cases have been recorded either in this country or abroad.

Dr. F. PARKES WEBER showed Microscopical Specimens illustrating an Apparent Thickening of Subcutaneous Veins. Dr. Weber said that if the superficial veins in a series of rather thin cachectic men, especially those slightly under the middle age, were felt, it would be found that in some of them the veins apparently had thickened walls, and indeed occasionally they can be rolled about like cords under the finger. As far as Dr. Weber had been able to obtain microscopical examinations he concluded that what clinically appeared to be "phlebosclerosis" was in these cases due to great development of the longitudinal unstriped muscle fibres in the most internal portion of the tunica media, and possibly also a state of contraction of the circular muscle fibres. To decide how far this condition is abnormal required further careful investigation. The condition was more noticeable in the internal saphenous veins than in the veins of the upper extremities. In the case of a man who had had syphilis two and a half years before his death (from ulcerative endocarditis) Dr. Weber found this condition to be associated in one of the internal saphenous veins with a certain amount of endophlebitis proliferans. During life the internal saphenous veins in the thighs felt like hard cords. When the veins in this case were cut open longitudinal folds were noticed similar to those described by Cornil in commencing varicose veins.—Dr. LAZARUS-BARLOW thought that caution should be observed in accepting these changes as actually due to morbid change during life. In some recent work on the lungs he had been struck with the ease in which, owing to particular methods of preparation, appearances exactly like endarteritis and endophlebitis could be produced.—The PRESIDENT also thought that it would be worth Dr. Weber's while to make preparations from normal veins. It had struck him that possibly if the veins were kept slightly distended during hardening, to the same extent as during life, that many of these appearances would not exist.

The following card specimens were shown:—

Mr. T. D. LISTER: Acute Œsophagitis in Infants.

Dr. COLCOTT FOX: Molluscum Contagiosum on the Legs of a Chicken.

Mr. H. J. CURTIS: Lipoma in the Perineum.

Mr. SHATTOCK: Guinea pigs Inoculated with (*a*) Streptococcus Pyogenes. (*b*) Coli Bacillus, (*c*) Tubercle Bacillus, and (*d*) Plague Bacillus.

Mr. C. P. WHITE: Ununited Fracture of the Scapula.

Dr. F. P. WEBER: Papillomatous Adenoma of the Kidney.

The annual general meeting was held subsequently when votes of thanks were passed to the retiring officers and members of council. The following gentlemen were elected for the ensuing year: President: Dr. Joseph Frank Payne. Vice-Presidents: Dr. Radcliffe Crocker, Dr. Frederick Taylor, Dr. F. Charlewood Turner, Dr. German Sims Woodhead, Mr. Anthony A. Bowlby, Mr. Stanley Boyd, Mr. Alfred Pearce Gould, and Mr. Robert William Parker. Treasurer: Dr. Sidney Coupland. Honorary secretaries: Mr. D'Arcy Power and Dr. Humphry D. Rolleston. Council: Dr. John Abercrombie, Dr. J. Rose Bradford, Dr. Julius Dreschfeld, Dr. Archibald E. Garrod, Dr. Herbert P. Hawkins, Dr. R. G. Hebb, Dr. William Hunter, Dr. H. A. Lediard, Dr. Hubert Montague Murray, Dr. G. Newton Pitt, Dr. J. W. Washbourn, Mr. William H. Battle, Mr. Cecil F. Beadles, Mr. Raymond Johnson, Mr. John R. Lunn, Mr. H. Betham Robinson, Mr. W. G. Spencer, Mr. J. H. Targett, Mr. Frederick C. Wallis, and Mr. Edgar W. Willett.

CLINICAL SOCIETY OF LONDON.

Cases of Intussusception.—Perforation of the Vermiform Appendix in Ambulatory Typhoid Fever.

A MEETING of this society was held on May 13th, the President, Mr. LANGTON, being in the chair.

Dr. DAVID B. LEES and Mr. A. QUARRY SILCOCK related a case of Ileo-cæcal Intussusception in which excision of involved intestine was performed with a successful result. A boy, aged four and a half years, was admitted to St. Mary's Hospital in December, 1896, on account of intussusception. Under an anæsthetic 28 oz. of water were injected into the rectum and reduction was apparently effected. He was discharged from the hospital two days later (on Dec. 30th). On Jan. 1st, 1897, he was readmitted, the symptoms having recurred with reappearance of the tumour. Reduction was again effected by injections of water. Again and again the tumour reappeared with symptoms as before, which subsided more or less completely under treatment. In the latter part of February and in March the abdominal pain became more constant; castor oil and rectal injections were frequently used to combat the constipation. At the end of March the condition of the boy became very serious. The tumour was now never wholly reducible and operation was determined upon. It was found that the parts concerned in the intussusception were the lower end of the ileum and the cæcum. The intussusception was irreducible and these were therefore excised, the ileum being divided 2 in. or 3 in. above the ileo-cæcal valve, the colon some inches below the cæcum. The cut ends of the intestines were approximated and united by Lembert and quilt sutures. The patient made an uninterrupted recovery and at the present time (May, 1898) is quite well. Examination of the specimen showed that the posterior wall of the cæcum carrying with it the appendix had been invaginated into the ascending colon; the ileo-cæcal valve had been dragged upon, carrying with it about 1 in. of the ileum. Dr. Lees and Mr. Silcock were unable to explain the mechanism by which the intussusception was brought about. The form of the intussusception seemed to belong to the same category of cases as those in which an inversion of the appendix into the cavity of the cæcum has obtained. In this case the wall of the cæcum carrying with it the appendix seems to have been the starting point of the mischief. It was clear from an inspection of the specimen that the complete reduction of the intussusception by the injection of air or water was an impossibility.

Dr. W. S. COLMAN and Mr. T. H. KELLOCK related a case of Chronic Intussusception of the Cæcum with Extreme Latency of Symptoms. The patient was a boy, aged eight years, who was admitted to the Hospital for Sick Children, Great Ormond-street, on Aug. 17th, 1897, on account of periodical abdominal pain and wasting. The paroxysms of pain had been noticed for fifteen weeks and were usually attended with vomiting. His bowels had been opened once or twice daily, the motions being solid. On admission he was thin, but his abdomen was full and somewhat resistant. There was a moveable swelling in the left flank between the iliac crest and the costal margin. It appeared to vary in size during the examination. An hour later during an attack of pain the mass became larger and harder and almost reached the middle line. In the attacks which frequently recurred the boy always placed himself on his hands and knees. It was thought at first that the case might be one of axial rotation of a wandering spleen, but later the splenic dulness could be mapped out as distinct from that of the tumour. The severe attacks of pain returned almost daily, but there was no change in the character of the motions and nothing could be felt *per rectum*. The boy was getting up and except for the attacks of pain appeared to be perfectly well until three weeks after admission and eighteen weeks after the onset of symptoms, when the vomiting and pain became severe and his general condition became serious. The character of the tumour was more definitely sausage-shaped and one end of it could be felt to be very hard. It was therefore decided to open the abdomen and this was done by Mr. Kellock on Sept. 13th. There was no free fluid in the peritoneum and no peritonitis. A large intussusception in the transverse colon and splenic flexure was found in the left hypochondrium. This was easily reduced at first, but owing to œdema and induration of the last two inches there was much more difficulty. A perforating ulcer with discoloured edges was found close to the root of the vermiform appendix. The ulcer was excised, the edges being brought together by Lembert's sutures. The cæcum was then returned to the abdomen. Two days afterwards, as there was pyrexia and tenderness over the cæcum, the wound was reopened at the lower end and some pus was liberated, but the child died. Leave for a post-mortem examination was refused. Attention was drawn to the latency of the symptoms, the bowels acting naturally throughout, and to the great variations in the size and position of the tumour. In any similar case it was suggested that if an ulcer had to be excised a fresh opening should be

made in the right iliac fossa and the cæcum stitched in position there.

Dr. LEES described a case of Intussusception of six weeks' standing successfully treated by Irrigation and the Local Application of an Icebag. A boy, aged three years, had suffered for six weeks from abdominal pain severe enough to make him scream. There had been no blood in the motions and vomiting had occurred only during the last of the six weeks. His appetite was very bad and he was wasting. A transverse swelling was detected in the position of the transverse colon which, while handled, became distinctly harder and firmer, afterwards softer again, obviously from peristaltic action. Under chloroform the tumour was felt more easily and the peristaltic hardening was still more evident. 25 oz. of water were passed into the rectum under low pressure and soon the tumour became shifted towards the right. The irrigation was repeated but apparently without further effect. A good deal of mucus came away but no blood. A few hours later the swelling occupied a vertical position in the line of the ascending colon; evidently the reduction was incomplete. Remembering that in fatal cases of intussusception most difficulty is experienced in reducing the last half-inch which is swollen through congestion, Dr. Lees applied an icebag over the cæcal region, taking care to keep the child's feet and legs warm with hot-water bottles. The icebag was kept in place for eight days; it was well borne, but hot fomentations were occasionally applied over the bladder to assist micturition. After the ice had been applied for four days the tumour was found to be less distinct. Three days later only a small rather hard lump, somewhat resembling a gland, could be detected. The appetite had greatly improved and during the week the child gained 2 lb. in weight. After eight days the ice was removed and another large enema was administered; this produced a copious motion. The small lump could now no longer be felt. Recovery was complete, and five months later it was found that the boy was still quite well and nothing abnormal could be detected in his abdomen. In this case, though the symptoms were subacute, the history of severe abdominal pain for six weeks, the characteristic position and shape of the tumour, the peristaltic hardening, and the effect produced by irrigation left no doubt as to its nature. It is well worthy of note that the intussuscepted intestine, even after six weeks, had not become fixed by adhesions and that it was still possible to obtain a very definite amount of reduction by irrigation. Yet it would probably have been necessary at last to open the abdomen if it had not been for the assistance rendered by the icebag, which apparently reduced the congestion of the wall of the intestine and allowed a final enema to complete the reduction. Dr. Lees admitted that there was a difficulty in the adoption of this method of treatment in an acute case of intussusception because of the marked tendency to collapse, but he considered the plan worthy of further trial in subacute cases.—Mr. BARKER congratulated Mr. Silcock on his success in saving by resection a case of intussusception which was in so severe a condition. Such a result was very rare. The most important question raised by this interesting series of cases was that of the desirability of resorting to injection or of proceeding at once to laparotomy. It was true that some cases got well with injection alone, but there were many in which from the outset such a procedure was hopeless. In a series of cases of intussusception brought before that society early in the session he had shown that out of 15 consecutive cases in which he had performed laparotomy for this condition no less than 3 were cases of enteric or ileo-colic intussusception which could not possibly have been reduced by injection. Five of his cases died, three of them being gangrenous at the time of operation. The results he had obtained encouraged him to earlier and freer operation in the future. He considered injection inadvisable as it not only involved delay but was not without risk, and he was convinced that immediate operation was the best mode of treatment in the average hospital case. In one of his cases there had been a thickening of the cæcum similar to that described by Dr. Colman and Mr. Kellock in their case. It was only by squeezing and a sort of massage that he was able to reduce the tough wall and keep it reduced. He did not think that there was much risk of recurrence after reduction. He thought that many of the apparent exceptions to this rule were cases in which reduction had been incomplete. He had, however, seen one case in which recurrence took place some months after operation. He mentioned one case in which on opening the abdomen he found a mass in the transverse colon which was at first thought to be the intussusception, but which proved to be a tuberculous mass, the real intussusception being found in the right iliac region. Although the intussusception in this case was an enteric one there was no vomiting.—The PRESIDENT thought that most surgeons would agree that in acute cases injection only gave rise to delay and often to a false sense of security when the intussusception had not been completely reduced. Even in chronic cases rupture might be caused by irrigation at low pressure. The operation in itself was not so dangerous as the delay and the nature of the disease. When injection was employed, too, it was impossible to feel whether the all-important last portion of the intussusception had been completely reduced.—Dr. LEONARD GUTHRIE said that diagnosis came before treatment and was often a matter of great difficulty. Some years ago he had had a boy, four years of age, under his care for some weeks suffering from paroxysmal abdominal pain. He had repeatedly examined the patient but could find no tumour either during the paroxysm or in the intervals. He never passed blood or mucus, but one day he was brought to the hospital with the ileo-cæcal valve protruding from the anus. He thought that a condition of "incipient intussusception" had been present all along and that from time to time spontaneous reduction had taken place and that strangulation and severe symptoms had occurred acutely. He agreed that in acute cases irrigation was unwise seeing that one was in the dark as to the condition of the bowel.—Dr. F. J. POYNTON said that it was often impossible to make a correct diagnosis unless the patient was seen at very frequent intervals. In the absence of blood and mucus in the stools the diagnosis would rest on the presence of a tumour of variable resistance, shape, and position which disappeared from time to time, reappearing with a fresh attack of abdominal pain.—Mr. SILCOCK, in reply, said that injection had been employed in the first instance in his case because at that time the tumour was of very recent formation and was freely moveable.—Mr. KELLOCK, in reply, said that he did not think that so little risk was involved in opening the abdomen in a child as had been suggested. The experience at Great Ormond-street was that in young infants laparotomy was an extremely dangerous operation no matter for what purpose it was performed. The risk might be minimised by making the smallest possible incision and introducing one, or at most two, fingers as Mr. Barker had suggested. Since this paper was written he had operated on another case of intussusception of the cæcum into itself. In this case also the child assumed the unusual genupectoral position. The intussusception was reduced and the child made a good recovery.—Dr. LEES, in reply, concurred in the view that peritoneal operations on young children were attended by great risk. He had not seen such favourable results after operation as Mr. Barker had obtained, but, on the other hand, he had seen many cases in which recovery had taken place in acute cases after injection alone. In many, surgical operation, performed immediately after injection had failed, had been equally unsuccessful.

Dr. ROLLESTON recorded a case of Perforation of the Vermiform Appendix during the course of Enteric Fever. The patient was a man, aged twenty-one years. Twelve hours after admission to St. George's Hospital with enteric fever abdominal pain and signs of collapse came on. After palliative treatment by morphia it was decided that perforation had probably occurred; the liver dulness remained, and it was thought that the perforation had been small and not allowed of the entry of gas into the peritoneum. Mr. T. Pickering Pick performed laparotomy and found fibrinous peritonitis due to perforation of the appendix close to the cæcum. The appendix was removed, the stump being invaginated into the cæcum, the peritoneum was washed out and a tube left in for drainage. On the next day the Widal reaction was found by Dr. C. Slater to be strongly marked. The patient rallied temporarily after the operation, but died on the second day, this fatal result being probably due to grave constitutional symptoms and to the fact that he had been at work to within five days of his death. At the necropsy ulceration of the intestine of a typhoid character was found. The points of interest in the case were (*a*) the frequency of appendicular lesions in enteric fever and (*b*) the question of operative interference during the height of the fever. In 14 out of 60 fatal cases of enteric fever examined in St. George's Hospital the appendix was found to be altered, being

swollen in 5, ulcerated in 7, and perforated in 2. In those 60 cases perforation (including the appendix cases) occurred in 18, so that the appendix was perforated in 11 per cent. of cases of entire perforation. This was the percentage arrived at by Nacke; Osler found it even higher (4 in 16), while Finney placed it at 5 per cent. and Fitz at 3 per cent. The statistics of operative interference in perforation during enteric fever were referred to and 2 recent cases reported by Deaven in which a perforated appendix was successfully removed during enteric fever were mentioned.—Dr. E. W. GOODALL was surprised to hear that the complication was so frequent. Although he had a somewhat extended experience of enteric fever at the fever hospitals he had not yet come across a single case. He had seen one case of operation for perforation in enteric fever. The patient was a girl, eight years of age, who was suffering from a recrudescence of enteric fever. She was exceedingly ill and the operation was somewhat prolonged owing to difficulty in finding the site of the perforation. It was also noticeable that there was little sign of the other typhoid ulcers from the outside of the gut, although they were shown after death to have been numerous. The aperture was closed by sutures. The patient lived four days. It was found that not the slightest attempt at repair had taken place and another perforation had been caused by one of the sutures having been passed through an adjoining ulcer. He agreed with Mr. Bland Sutton that it would be better in such a case to bring the perforation up to the abdominal incision and fix the gut there. Dr. Goodall mentioned that Mr. Parkin of Hull had operated successfully in one case of perforation and there were two more successful cases in the recent reports of the Belvidere Hospital, Glasgow.—Mr. BARKER took exception to the wording of a statement that "the mortality after surgical treatment was appalling." The cases without operation might be considered as uniformly fatal, while after operation 23 per cent. had recovered, which was encouraging.—Dr. ROLLESTON, in reply, said that he had also been surprised to find that the condition occurred in so large a percentage of cases. Most of them were derived from American literature.

SOUTH-WEST LONDON MEDICAL SOCIETY.

The Proposed Midwives Bill.

A MEETING of this society was held at Wandsworth Town-hall on May 4th, under the presidency of Mr. T. A. I. HOWELL, to discuss the questions raised by the proposed Midwives Bill.

The PRESIDENT argued that among the reasons for the Bill were the facts that in a large proportion of the women attended by unskilled persons the mortality both among mothers and children was increased and that those cases also were responsible for much of the ophthalmia neonatorum which later drifts towards the hospital. For these and other reasons it is agreed on all hands that something ought to be done. In a general criticism of the Bill he pointed out the necessity for limiting the responsibility to the person who actually had the conduct of the case and called attention to the omission from the Bill of all reference to stillbirths and the absence of any clause making it necessary on the part of the proposed midwife to provide a certificate of character. He pointed out the necessity, in his opinion, of protecting the practice as well as the title of the medical man and of restricting the practice of the midwife solely to the functions which she was intended by the Bill to fulfil. He showed that by-laws cannot be made contrary to the spirit of the Act, which seems to be the case in the Bill under consideration. As regards local funds they ought not to be available for expenses incurred in carrying out the provisions of the Act, and he especially objected to Clause 9, which virtually appoints medical detectives. Public opinion, he was sure, was generally adverse to the passing of such a measure.

Mr. ROWLAND HUMPHREYS said that the proposed Bill was only there in outline and that the details were left to be filled in by the board. He assured the meeting that deputations representing 20,000 persons in favour of the Bill had been received and that petitions to the same effect were constantly being sent in. Legislation had been hampered to a great extent by the views taken of the matter by various women's societies. He thought that a certificate of character would be of no use and that it would be a very difficult thing to provide against the risk of the midwife practising for gain.

Dr. EDEN said that since the Bill had been condemned by the General Medical Council it ought not to be allowed to pass into law. The Bill should have been promoted by the profession at large and not by any particular body, no matter how good their intentions. At present there were no means of dealing with midwives who were deserving of censure; they were practically under no control. This was very different from the regulations on the Continent—in Italy, for example, where every midwife must give full particulars of each case which she has attended to the local authority. There, also, midwives are trained gratuitously, but in this country the probabilities are that the certified midwife will not reach the class for which she is intended—viz., the very poor.

Dr. MCCOOK WEIR said that if this Bill passed the midwives would ultimately treat all diseases of women and children. He stated that the signatures in favour of the Bill were obtained by canvassing, that in his opinion the constitution of the Midwives' Board was bad, and that the General Medical Council had been overridden by the Privy Council and by other influences. He gave an outline of a Bill prepared by himself which he would call the Obstetric Nurses Bill and was strongly of opinion that a certificate of character was a most essential qualification.

Dr. BARKWELL spoke against the Bill.

ÆSCULAPIAN SOCIETY OF LONDON.

The Management of Labour in Contracted Pelves.—Sacral Spina Bifida with absence of Skin Covering and with Skull Bones imperfect.—Spontaneous Complete Disappearance of Large Rheumatic Fibromata.

A MEETING of this society was held on May 13th, the President, Dr. B. G. MORISON, being in the chair.

Dr. THOMAS G. STEVENS read a paper on the Management of Labour in Contracted Pelves in which he related particulars of the following cases:—

Full-Time Children.

—	Primipara or Multipara.	Age.	Diagonal conjugate in inches.	Operation.	Weight of child.	State of child at birth.
1.	P.	22	3¼	Craniotomy. Prolapsed funis.	—	Stillborn.
2.	P.	32	3¼	Symphysiotomy and forceps.	—	Stillborn
3.	P.	22	3⅛	Craniotomy.	7 lb. 11 oz.	Stillborn.
4.	M. (7th)	30	3½	Version.	7 lb. 4 oz.	Alive.
5.	P.	31	3¼	Version and craniotomy.	9 lb.	Stillborn.
6.	P.	26	3⅜	Forceps.	7 lb. 5 lb.	Dead. Alive.
7.	P.	?	3½	Replaced funis.	4 lb. 8 oz.	Alive.
8.	P.	25	3	Version.	6 lb. 12 oz.	Stillborn; white asphyxia.
				Induction Cases.		
9.	P.	25	2½	6th month.	—	Stillborn.
10.	M. (2nd)	34	3⅜	8th month. Forceps.	—	Alive.
11.	M. (5th)	38	3	8th month. Version.	—	Stillborn.
12.	P.	—	—	5th month. Kyphotic pelvis.	—	Stillborn.
				Premature Labour not Induced.		
13.	M. (2nd)	25	3½	Version.	—	Alive.

All mothers recovered. 5 children were born alive and 9 were stillborn.

He emphasised the great inadvisability of hurry in these cases, pointing out that a maternal pulse of 110 per minute is safe unless the well-known signs of exhaustion in the parturient are present. For the child forceps delivery was better than version.

Mr. W. CAMPBELL M'DONNELL showed a drawing of Sacral Spina Bifida with absence of Skin Covering and the Specimen of the Defective Sacrum. The skull was also very imperfect, the frontal bones being separate 7·5 cm. On the fifteenth day the child had three epileptic fits and then died. Delivery had been quite normal.

Mr. M'DONNELL also read notes of the Complete and Spontaneous Disappearance of Fibromata, 2·5 cm. in diameter, of rheumatic origin, from a man, aged thirty-one years, the subject of previous acute rheumatism without cardiac lesion.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Risks to the Ureters when Performing Hysterectomy.

A MEETING of this society was held on May 12th, the President, Dr. MACNAUGHTON-JONES, being in the chair.

The following specimens were exhibited:—

Mr. J. FURNEAUX JORDAN: Myoma of the Uterus removed by Hysterectomy.

Dr. GRANVILLE BANTOCK: Uterine Fibroid removed by Hysterectomy.

Mr. CHARLES RYALL: Large Uterine Fibro-myoma removed by Abdominal Hysterectomy.

Mr. F. BOWREMAN JESSETT: Uterine Fibroid Complicating Pregnancy.

In the discussion on these four specimens the following gentlemen took part: Dr. HEYWOOD SMITH, Dr. PURCELL, Dr. NEIL MACPHATTER (Denver, Colorado), Dr. ARTHUR GILES, and the PRESIDENT.

The following card specimens were exhibited:—

Mr. W. D. SPANTON (Hanley): Biliary Calculus.

Dr. T. DOLAN (Halifax): Intra-uterine Myoma.

Dr. F. A. PURCELL read a paper on the Risks to the Ureters when Performing Hysterectomy, illustrated by a case in which both ureters were occluded and freed fifty-eight hours after. He dealt with the risks to the ureters when performing abdominal hysterectomy in which the combined method is employed—in other words, pan-hysterectomy—illustrating his remarks by quoting a case and showing the specimen of a large adeno-carcinoma of the uterus with a diseased os and a much enlarged and widely distended neck. During the operation both ureters became compressed and no urine was voided from the bladder. Fifty-eight hours after the first operation the patient was anæsthetised and the abdomen was again opened, the laced peritoneum across the floor of the pelvis, which was intact and free from inflammation, was ripped asunder and the ureters were examined. Both were found to be ballooned. The silk ligatures on the uterine arteries were cut through and removed; by this means the patency of the ureters was restored and urine flowed into the bladder, the toilet was again performed and eventually the patient made an uninterrupted recovery. Dr. Purcell then reviewed the relations of the uterine arteries and the ureters and stated that one, if not the greatest, risk that presented itself in performing pan-hysterectomy was the endangering of the ureters. He regarded the uterine artery as being the most important vessel surgically, running its course downward and inward between the folds of the broad ligament until it arrives at a point below the level of the os internum just above the lateral fornix, where it makes a sharp turn across the ureter to the neck.—Mr. BOWREMAN JESSETT said that Dr. Purcell's case was interesting from many points of view and, among others, from that of diagnosis. The question lay between malignant disease and a sloughing fibroid; and the conclusion, which was borne out by the operation, was that it was a sloughing fibroid which was becoming malignant. One lesson from the case was that it might have been better to divide the arteries and tie them after the removal of the tumour. The ureters were not included in the ligatures, but were kinked by the puckering up of adjacent tissues.—Dr. GEORGE KEITH related a case which he had seen in Edinburgh some fifteen years previously, in which a small piece of tube was found on an ovarian tumour after its removal. It was sent to a pathologist to be examined and he reported that it was not ureter. However, the necropsy showed that a piece of ureter had really been removed.—Dr. NEIL MACPHATTER had had trouble with a ureter in his first hysterectomy. The tumour was very large, weighing 46 lb. after removal, and was operated upon under the impression that it was ovarian. While separating adhesions a uniform band was noticed and he was about to divide it when his assistant suggested that it might be ureter. This timely suggestion saved the patient. The ureter had become so much elongated by the tumour that after it was freed it lay in a little coil.—The PRESIDENT observed that in these cases the normal relations were so disturbed that exact anatomical knowledge might be of little avail and injury was generally due to displacement or congenital anomaly of the ureter. In Doyen's method of pan-hysterectomy the risks to the ureters were minimised, especially because he adopted the plan of drawing the uterine and ovarian arteries out of the surrounding tissues, securing the vessel alone. He had written to several eminent operators asking their experience with the ureter. Howard Kelly had promised to send statistics, and Martin of Berlin, Doyen of Paris, and Kufferath of Brussels had written giving their experience. These letters the President read. To Howard Kelly, whom they had had the pleasure that evening of proposing as a Fellow of the society, they were indebted for some of the most important advances in the protective and reparative surgery of the ureters. To him was due the method of ureterostomy and through his work on the Catheterisation of the Ureters they were able to determine which kidney was affected in cases where nephrectomy was required, thus obviating the necessity of a preliminary abdominal section. He congratulated Dr. Purcell on his boldness and success under very trying circumstances. — Dr. C. H. F. ROUTH suggested that when uræmic symptoms threatened and there was reason to fear injury to the ureters it might be advisable as a preliminary step to open the kidney from behind. By this means present danger could be averted and a secondary operation could be performed later if necessary.—Dr. PURCELL, in reply, thought that when the injury to the ureter was discovered at the time of operation Dr. Routh's suggestion might be adopted with advantage. But if it were not found out till later it would be necessary to first determine which side was affected. As a rule, if one side only were injured the remaining kidney would go on excreting and there would then be no danger of uræmia.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Combined Pleural and Pericardial Adhesion.

A SPECIAL meeting of this society was held on April 27th, Dr. CATTLE, President, being in the chair.

Dr. FREDERICK TAYLOR read a paper on Combined Pleural and Pericardial Adhesion. Dr. Taylor described the case of a woman, aged forty-two years, who was admitted to hospital for dyspnœa, cough, and pain in the chest. Five months previously she had noticed that her abdomen was getting larger. A month previously she had chills, shivering, dyspnœa, pain between the shoulders, and cough. Œdema of the legs followed and the physical signs of fluid at the right base. This was explored without result. On admission the physical signs of right pleural effusion persisted and the left base presented the same in less degree. The heart's impulse was felt in the normal position. The dulness was normal in extent. The pulse was regular, but feeble and rather rapid. There was no murmur. The urine a few days later contained some albumin. The patient never improved. The general condition and physical signs remained much the same, but the dyspnœa increased as well as the anasarca. She died about six months after admission. The post-mortem examination revealed universally adherent pleura and adherent pericardium. The lungs were compressed and airless except at the apices. Some bronchial tubes were dilated. The vessels and other structures in the mediastinum were matted together by inflammatory tissue (mediastinitis). The peritoneum was universally thick and opaque and presented some recent lymph as well. The right auricle was dilated, the right ventricle was dilated and hypertrophied, and the left ventricle was very small. Dr. Taylor pointed out that the mere

co-existence of pericardial and pleural adhesions was common as found post mortem, but a very small proportion of them seem to present the features seen in this case—great prominence of the physical signs on the side of the pleura and absence of local evidence on the side of the heart. The etiology of this case was obscure. There was no history of rheumatism or acute pneumonia, and other causes of multiple serous inflammations were not present with the exception of scarlet fever. The consideration of the relation of the different serous inflammations to one another and to the symptoms showed that the pulmonary lesion seemed unequal to the production of the symptoms except through the failure of the right heart and no doubt the dilatation of the right cavities as a result of adherent pericardium was the chief cause of the dropsy. Dr. Taylor referred to an interesting paper by Heidemain, who showed that ascites was likely to occur as an early symptom in adherent pericardium, probably because there had been with the pericarditis simultaneous peritonitis. This had a possible bearing upon the present case. The subject of mediastinitis was then discussed and its probable influence on the symptoms in this case was shown to be small. In the diagnosis Dr. Taylor suggested that the co existence of lesions in two or more serous membranes as the result of former inflammations rather increased than lessened the difficulties in diagnosis, especially in consideration of the interaction of the heart and lungs one upon the other. The chief guide is probably the recognition of adherent pericardium acting upon the right heart as a possible cause of failing circulation. When the local evidence of heart disease is not forthcoming the suspicion of adherent pericardium may be strengthened by evidence that the pleura is, or has been, inflamed. Dr. Taylor referred in conclusion to another case in which a similar diagnosis seemed allowable.

The PRESIDENT thanked Dr. Taylor for his interesting address and Dr. HANDFORD proposed and Mr. CHICKEN seconded a vote of thanks to Dr. Taylor which was carried unanimously.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Exhibition of Cases and Specimens.—Empyema of Fronto-ethmoidal and Sphenoidal Cavities.

A MEETING of this society was held on May 11th, Mr. C. E. RICHMOND, President, being in the chair.

The PRESIDENT showed and described a case of Fibro-adenoma in a Breast the seat of chronic mastitis.

Dr. REYNOLDS and Dr. MOORE showed specimens from a case of Acute Hæmorrhagic Pancreatitis met with in a male subject, aged twenty-nine years. During life the patient had suffered from several pseudo-angina-like attacks. The fatal termination was very sudden, being ushered in by somewhat anomalous mental symptoms. The pancreas, examined nine hours after death, was enlarged, weighed 146 grammes, was firm, and of a bright red colour mottled with dark grey and yellowish patches. The duct was patent and normal in size. Microscopically the peri-glandular fat showed areas of necrosis and masses of decolourised and more recent blood-clot; the gland parenchyma in many parts appeared but little altered, the individual acini being more widely separated than normal; in other parts it was in a condition of coagulation necrosis or had disappeared entirely, its place being occupied by a necrotic débris. The interstitial tissue was the seat of considerable exudation, having decided hæmorrhagic characters and here and there small foci of suppuration. In the necrotic areas the bacillus coli communis was found both by cultivation and histologically, but no other organism. The first part or the duodenum was the seat of an acute necrotic inflammation, the mucous membrane being necrosed and in great part absent, the submucous and muscular coats being markedly infiltrated and congested.

Mr. E. STANMORE BISHOP showed several Microscopic Sections of a Non-gravid Tube from a case of Ectopic Pregnancy in order to illustrate the changes described by Webster of Montreal. For purposes of comparison sections of ordinary decidual membrane of a normal and of an inflamed Fallopian tube were also shown, these having been kindly lent by Dr. Fothergill. Other sections were shown from the gravid tubes of both cases showing chorionic villi and one mucous fringe with well-marked decidual change. Mr. Bishop detailed the changes found in these tubes, the differences between such changes and those found in ordinary salpingitis, and emphasised the fact that if these observations were confirmed a clear idea would be obtained as to the causation of such cases and a scientific reason for the commonly accepted belief that all ectopic pregnancies are primarily tubal.

Dr. KELYNACK showed a specimen of Dissecting Aneurysm of the Thoracic and Abdominal Aorta which developed in a female, aged fifty years. There was a history of strain from which the cardiac symptoms dated. Death was due to progressive cardiac failure. The aneurysm originated by a slit-like aperture in the descending thoracic aorta and reached to the common iliac arteries. There were several communications between the sac and the aorta.

The following card specimens were exhibited:—

Mr. STANMORE BISHOP: (1) Ureteral and Vesical Calculi; and (2) Pyosalpinx.

Dr. FOX EDWARDS: Flattened Bullet removed from the Nasal Bone.

Dr. HARRIS: Aortic Aneurysm compressing the Trachea from a Female Subject.

Dr. HIGGINSON: Supernumerary Digit.

Dr KELYNACK: Aortic Malignant Endocarditis from a Medico-legal Case.

Mr. RICHMOND: Cerebellar Abscess following Mastoid Disease.

Dr. STEELL: Melanotic Sarcoma of the Liver and Kidney.

Mr. WESTMACOTT: (1) Localised Tubercle of the Vocal Cords; (2) Carcinoma of Sinus Pyriformis; and (3) Trauma of the Larynx in a Sword-swallower.

Mr. WOLSTENHOLME: Epithelioma of the Glans Penis in a Horse.

Mr. WESTMACOTT read a paper on the Pathological Anatomy of Empyema of Fronto-ethmoidal and Sphenoidal Cavities. After demonstrating the anatomical limits of the cavities met with in different skulls, both in the recent state and macerated condition, the appearances of the part when filled with pus were described as seen through the nasal speculum and with the rhinoscopic mirror. Finally, a few points of interest in differential diagnosis and operative treatment were detailed. A number of prepared specimens and photographs were shown.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Rupture of the Vagina during Labour.

AN ordinary meeting of this society was held at Owens College, Manchester, on April 22nd, Dr. J. W. MARTIN, the President, being in the chair.

Mr. RUMBOLL (Leeds) showed a large Fibroid Tumour of the Uterus removed by Abdominal Hysterectomy. Treatment by electrolysis had failed to have any effect on the growth. In removal the "serre-nœud" was used and the stump was brought to the incision.

Dr. DONALD (Manchester) showed the Uterus and Appendages which he had removed from a patient, about thirty years of age, who had been suffering for eight months from Acute Pelvic Inflammation. On the left side the ovary was represented by a thick-walled abscess of about the size of an orange; the tube was thickened and its abdominal end was blocked and adherent to the abscess. On the right side the tube was elongated and much thickened and the abdominal end was closed and studded with small caseous patches; the right ovary was small and was embedded in adhesions. The uterus was enlarged and globular and the walls were much increased in thickness. The patient was unfit for work, was almost entirely confined to bed, and had suffered from hæmorrhage constantly for four months. After palliative treatment in the hospital for four weeks without any change in her condition operation was decided upon and the vaginal route was chosen. Both tubes were useless from purulent inflammation, and the mischief having evidently commenced in the endometrium extirpation of the uterus was thought best. Dr. Donald remarked that the radical vaginal operation for bilateral tubal and ovarian suppuration had not so far met with much support in this country, although for some years it had been recognised on the Continent as the best means of dealing with cases which did not improve under rest and palliative treatment. The removal of the uterus added nothing to the danger of removing the appendages. After removal of the appendages the uterus was a useless organ and the objections to its removal were

mainly sentimental. When the uterus was healthy and the appendages were not septic there was no need to remove it.

Dr. DONALD then read notes of a case of Rupture of the Vagina during Labour. The case was that of a woman, about forty years of age, who had in her ninth confinement been attended by a midwife. When the patient was admitted to the hospital a very distended and congested loop of large intestine 2 ft. in length was hanging from the vagina; the funis was prolapsed, cold, and pulseless. There was a large rent in the posterior vaginal wall; the cervix was about two-thirds dilated, the vertex presenting in the right occipito-anterior position. Craniotomy was performed and after the extraction of the fœtus and the expulsion of the placenta it was found that the tear in the posterior vaginal wall began at a point 1 in. from the posterior commissure of the vulva, ran transversely for about 2 in., and then almost vertically and a little to the left of the middle line up to the highest point of the posterior vaginal fornix. The uterus was loosely packed with iodoform gauze and the hole in the vaginal vault was plugged with several thick strips of iodoform gauze which were removed from the uterus fifty-six hours after delivery, but not from the abdominal cavity until the seventh day. The patient made an uninterrupted recovery.

Dr. W. K. WALLS (Manchester) described a case similar to Dr. Donald's but less severe. It was that of a patient in her eighth confinement with conjugata vera of 3¾ in. and with a history of having borne large children and of having had forceps labours. The breech was impacted, chloroform was administered, and a leg was brought down; the arms were delivered with difficulty, the head extraction being comparatively easy. A laceration was discovered in the neighbourhood of the right sacro-iliac synchondrosis external to the cervix; the laceration admitted two fingers which passed into the tissue of the broad ligament and then into the peritoneal cavity. The tear was plugged with iodoform gauze, the cervix uteri was plugged separately, and the vagina was tightly packed with iodoform gauze beneath all. A good recovery was recorded.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Discussion on Obstetric Report of Rotunda Hospital.—Exhibition of Specimens.

A MEETING of this section was held on April 27th, the President, Dr. F. W. KIDD, being in the chair.

Dr. R. D. PUREFOY having read the Clinical Report of the Rotunda Lying-in Hospital for 1896–97,

Dr. MACAN said that as an old master he would like to offer his congratulations to Dr. Purefoy upon the success of his first year. He did not agree with Dr. Purefoy in his four hours' teaching of putting on forceps in the second stage. He thought that every student should be given absolute indications for putting on forceps. As regards morbidity, the limit of normal during his mastership was 100·4, instead of 100·8 as at present. He was tolerably content with the treatment of eclampsia by chloroform and chloral hydrate in large doses. There was no objection against morphia as well.

Dr. A. SMITH said that if the mother's temperature was raised and her pulse was quick, or if the child showed pressure effects, such as quickening or slowing of the heart, and meconium was passing away, with vertex presenting, the forceps should be used.

Dr. SMYLY was struck with the steady increase in the deliveries in the Rotunda Hospital. There was also a decrease in the mortality, mainly due to antisepsis and asepsis, but also due to the discipline in the hospital. Results in private practice were not at all commensurate with those in hospital practice, chiefly, he thought, due to the rules being carried out in a perfunctory manner. Regarding mortality, in contrast to the results of late years, he read the following from an old Rotunda Hospital report:—

In 1869	there were	1159	deliveries with	25 deaths.
,, 1870	,,	1087	,,	27 ,,
,, 1871	,,	1161	,,	33 ,,
,, 1872	,,	1193	,,	20 ,,

The PRESIDENT said that formerly the fact of a man being master of a lying-in hospital was against his private practice on account of his being daily in touch with septic cases. Now, however, as shown by statistics, a lying-in hospital was the safest place for a woman to be delivered in. He thought there was some serious mismanagement in connexion with private cases, probably because the nurse did not carry out the rules as she would under a matron in hospital. Regarding the removal of retained membranes not accompanied by hæmorrhage he thought it better not to introduce the hand to remove such.

The following specimens were shown:—

Dr. W. J. SMYLY and Dr. R. D. PUREFOY: Myomatous Uteri.

Mr. E. H. TWEEDY: Ovarian Cyst removed by Cœliotomy.

BOMBAY MEDICAL AND PHYSICAL SOCIETY.

Adjourned Discussion on Plague Experiences at Hubli.

A MEETING of this society was held in the University Hall on March 25th, Surgeon-Lieutenant-Colonel J. W. CLARKSON being in the chair.

The adjourned discussion on Surgeon-Captain C. H. L. Meyer's paper on Plague Experiences at Hubli, of which an abstract appeared in THE LANCET of April 2nd, p. 936, was resumed.

Surgeon-Captain J. B. SMITH, acting civil surgeon, Poonah, sent some remarks, read by the Secretary, in which a comparison was drawn between Hubli and the village of Karad in the Satara district. The circumstances of the two places were very different. In Hubli there were 35 cases all told; in Karad the week before Surgeon-Captain Smith went to it there were over 35 cases a day. In Hubli the people affected were railway employés and were under considerable control; the people at Karad were subject to a punitive police post owing to a threatened attack on the assistant collector. In Hubli dry weather accommodation had only to be found for 1200 people, close to a line of railway; in Karad, four miles from the railway, with an unbridged river in flood between, monsoon—i.e., rainy season—accommodation would have had to be provided for at least 6000 people. Evacuation of the houses seems to be the only real remedy for plague in the villages but it is practically impossible during the rains.

Staff Surgeon BASSETT SMITH said that on two occasions a single case among the natives was attacked in the *Tenasserim*, one in each epidemic. They were quickly removed to hospital and the part of the ship was well scrubbed with disinfectants. On neither occasion was there any spread of the disease.

Dr. N. N. KATRAK, a sanitary member of the Bombay Municipal Corporation, said that measures of detention, quarantine, and segregation were always difficult of application, even in the beginning and in small places, but were almost impossible in such a large city as Bombay, especially when plague was extensively prevalent. He considered that rats were the chief if not the sole propagators of plague.

Dr. PEARSE said that the records show that not more than 5 per cent., and probably very much less, of those exposed to the contagion of a case of plague contract the disease, which seems to indicate that measures must be adopted to destroy the contagion from other sources than that from one individual to another.

Dr. ISMAIL JAN MAHOMED said he had noticed the recrudescence of plague in houses which were thoroughly disinfected and he thought this was due to the incoming tenants bringing with them dirty linen which infects the rats and then the rats spread the disease.

Surgeon-Major H. P. DIMMOCK, who spoke at considerable length, said that (1) the people should be removed from insanitary and unhealthy quarters; (2) the sick should be treated in hospitals; (3) those who had been in contact with the sick should be placed in segregation quarters for a certain time; (4) the clothes and belongings of the sick should be disinfected; and (5) the infected houses must be disinfected and allowed to stand empty for a considerable time. In a city it is difficult to carry out such measures even if the citizens honestly coöperate, and in Bombay, where they are largely hostile, the difficulties are enormous. He did not think that the epidemic was spread by rats so much as was imagined.

The further discussion was postponed till the next meeting.

Reviews and Notices of Books.

The Medical Examination for Life Assurance. By F. DE HAVILLAND HALL, M.D, F.R C P. Lond. Bristol: John Wright and Co. 1898. Price 2*s.* 6*d.* net.

THIS volume contains much that is sensible and practical in the way of advice as to the formation of a correct judgment upon the prospects of life of individuals presenting themselves for insurance. The medical examiner has often a difficult task to perform in estimating aright the importance of factors in the family history, in the previous health-condition of the applicant, his state at the time of application and his manner of life and occupation. It is not humanly possible to forecast with accuracy the vitality of any individual, but there are considerations under each of these heads which are clearly expounded by the author that should lead to the rejection or the "loading" of the application. Dr. de Havilland Hall exercises a wise caution in his recommendations, especially in regard to the subject of family tendencies, which certainly go for a great deal in estimating the chances of life. Speaking of "albuminuria," he considers that at present too little is known of the after-history of cases of "functional albuminuria" to render it safe for the examiner "to recommend for assurance any applicant whose urine contains albumin." However, a few lines further he somewhat modifies this view, for he says that if the subject is otherwise normal and free from a family history of Bright's disease and the urine is still found to be albuminous after a postponement of from three to six months, then "a further period of probation might be suggested or the applicant might be granted an endowment policy payable at fifty or fifty-five, an addition of about ten years being made." There are some judicious remarks upon the selection of an office, particularly addressed to medical men, whose profession renders it especially incumbent on them to take the opportunity of assuring themselves on embarking on their career in life.

Diseases of Women: A Clinical Guide to their Diagnosis and Treatment. By GEORGE ERNEST HERMAN, M.B., F.R.C.P. Lond., Obstetric Physician to, and Lecturer on Midwifery at, the London Hospital, &c. London: Cassell and Co., Limited. 1898. Price 25*s.*

THIS work is dedicated to the memory of Matthews Duncan and the equally remarkable man, Henry Gawen Sutton who was lecturer on pathology at the London Hospital and whose teachings must have greatly assisted in moulding the views of the writer of this volume who was a student at that school. A similar scientific spirit pervades the pages of his book to that manifested in Duncan's and Sutton's works—the same attempt to base practice on knowledge and scientific certainty and not on pure empiricism which unfortunately even at the present day is common in the treatment of the diseases of women and which has too long dominated this department. Dr. Herman's book is unique in this field, being neither a systematic textbook nor a volume of clinical lectures, but a "clinical guide" to the diagnosis and right treatment of the diseases of women. The sixty-three chapters of which the work consists are grouped into eleven parts not with any definite attempt at systematic arrangement, but rather in accordance with his clinical experience. He broadly divides the diseases peculiar to women into major and minor gynæcology. In the treatment of the former group surgical knowledge is especially necessary, whereas in the minor class the difficulties are medical and include "the treatment of slight ailments which interfere with the patient's comfort, but if she has fortitude to disregard this, neither impair health nor endanger life." Not being hampered by a too methodical arrangement of the work the author in the first seven chapters deals with subjects many of which are of general interest to the profession. Thus, in reference to the necessary training for the proper performance of surgical gynæcology he says: "The system at many of our hospitals by which the operations are in the hands of the seniors, and the juniors during the years most precious for the acquisition of manual dexterity are kept to seeing out-patients, is a bad one. It would be better for the seniors to see the out-patients and the juniors to do the operations." Would Dr. Herman support such a radical change in hospital organisation? The chapters on Neurasthenia, Hysteria, and Headaches may be studied with advantage by all practitioners, the discussion of the various forms of headache being worthy of one devoting himself particularly to the study of the nervous system and containing some caustic criticisms; thus in speaking of the supposed reflex effects of uterine diseases Dr. Herman says: "There have been publications—I trust now out of date—in which uterine paralysis, uterine cough, ovarian dyspnœa, &c., have been written about. The uterus and ovaries have been maltreated to cure these maladies. Such things cannot now be seriously discussed. They only mean that a patient with some organic disease has had the misfortune to meet with an incompetent doctor." The enumeration of the signs and symptoms and the differential diagnosis of uterine and ovarian tumours is clear and very methodical, and the directions for the performance of major operations are precise and may be safely followed. Dr. Herman's surgical principles are quite up to date, but fortunately he does not support those who advocate the removal of all fibroid tumours as soon as discovered. The volume contains 252 illustrations, most of them being derived from the usual sources. A few are far from satisfactory, as one on page 481 "of a patient of the author's," in which the anatomy of the external genitals has been quite disregarded by the draughtsman. This work is no mean addition to our English medical library and is sure to prove helpful, not only to advanced students who have already acquired a knowledge of the elements of gynæcology, but to general practitioners and as a book of reference to those who devote themselves to this branch of practice.

Pathological Technique. By Dr. FRANK BURR MALLORY, Assistant Professor of Pathology, Harvard University Medical School; and Dr. JAMES H. WRIGHT, Director of the Laboratory of the Massachusetts General Hospital. London: The Rebman Publishing Company, Limited. 1898. Pp. 397. Price 14*s.*

THIS work is intended to be a practical manual for the Pathological Laboratory. Most books of the kind in addition to a description of the various methods employed in such a laboratory contain the clinical or pathological deductions which may be made from the examinations. Such a plan has its advantages and disadvantages. In the work now under consideration a sort of compromise is made.

Part I. contains good and detailed instructions as to the making of post-mortem examinations. Some of the processes described are rather old-fashioned, but as a whole the student will derive many useful hints from a perusal of the first seventy pages of the book.

Part II. deals with Bacteriological Examinations. Not only are the methods for making culture media and the methods of studying bacteria fully explained, but excellent descriptions are given of the various forms of micro-organisms and numerous illustrations are distributed throughout the text. The great majority of these are borrowed from other authors, but are none the less valuable on that account.

Histological Methods are fully detailed in Part III. The

processes are clearly described and there should be no difficulty in following out the instructions given.

We can cordially recommend the work as a useful handbook for the laboratory, but nothing more. In order to learn the results which may be obtained from clinical and pathological observations we must search elsewhere.

Respiratory Exercises in the Treatment of Disease. By HARRY CAMPBELL, M.D., F.R.C.P. Lond. London: Baillière, Tindall, and Cox. 1898. Pp. 200. Demy 8vo. Price 7*s.* 6*d.*

THIS, like the author's other works, is characterised by independence of thought and opinion based on sound physiological principles to which reference is often made in the course of the argument. The present volume is, so to speak, a forerunner of a larger and more special one on the mechanical treatment of heart disease, a subject which has long engaged the author's attention; in fact, we gather from the preface that this form of treatment has occupied his thoughts since the commencement of his medical career and that he has found himself somewhat forestalled by the Nauheim school. The present volume is therefore somewhat of a preliminary contribution and is concerned rather with general considerations. In the first place it clears the ground by dealing at length with the physiological problems of respiration, then describes the various kinds of breathing exercises, and in conclusion treats more briefly of their practical application in various diseases.

The more interesting parts are those describing the breathing exercises and their therapeutic uses. Under the heading of preliminary exercises the patient is directed to learn to dissociate costal and abdominal breathing, since each produces its own peculiar effects. Active breathing exercises are described and directions for combining them with active exercises for the arms are given. By developing the lungs and chest respiratory exercises may prevent the onset of pulmonary disease or exert a beneficial influence on its course. With regard to the treatment of heart disease by respiratory exercises the author is rather brief, as he proposes to deal with it at length in a separate work which the reader of the present volume will await with interest.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held at 20, Hanover-square on April 27th, Dr. W. V. Snow being in the chair.—Dr. William Bain read a paper entitled "The Action of Certain Drugs and Mineral Waters on the Secretion and Composition of Human Bile: an Experimental Investigation," after which Dr. A. P. Luff, Dr. Solly, and Dr. Hobhouse made some remarks and Dr. Bain briefly replied.—Dr. Edmund Hobhouse then read a paper on Gout and Rheumatism in Relation to the Seashore and Salt-water Baths, in which he said that it seemed doubtful whether sea air in itself had any direct effect apart from the question of soil and general meteorological conditions. Season also is an important subject, for the seaside is drier and more free from fogs than the country during the autumn and winter, but more windy in the spring. Statistics seem to show that the sea has little influence on acute and subacute rheumatism, but generally speaking marine climates are not indicated in rheumatic affections, although patients weak and anæmic after acute attacks may be greatly benefited. Gouty patients with any active symptoms are better away from the sea. Salt-water baths are unquestionably of great value, especially in subacute rheumatism, but the question is whether their value is due to the heat or the salt—probably chiefly to the latter.—Dr. Archibald Garrod, Dr. Luff, Mr. Hamilton Cumming, Dr. Street, Dr. Hyde, Dr. Tyson, Dr. Solly, Dr. Ward-Humphreys, Mr. Bowen Davies, and Dr. Symes Thompson took part in the subsequent discussion.

Analytical Records
FROM
THE LANCET LABORATORY.

BYNO-PHOSPHATES.

(ALLEN AND HANBURYS, PLOUGH-COURT, LOMBARD-STREET, E.C.)

THE improvement in this preparation is evident. It consists simply of the replacement of the sugar in the ordinary preparations of chemical food by an active fluid malt. Whilst the phosphates of iron, lime, potash, and soda are preserved unimpaired the menstruum is not only itself nutritious but an aid to digestion. Preparations loaded with sugar are frequently inadmissible.

HYDROXYL-FREE COD-LIVER OIL.

(PETER MÖLLER, 43, SNOW-HILL, E.C.)

We have already shown how the elimination of hydroxyl by Mr. Möller's process of preparation renders cod-liver oil free from the decided drawback of "repeating" or giving rise to eructation. We have recently tested both chemically and practically a sample of the new season's oil (1898) with satisfactory results. The oil is remarkably bright and clear and practically tasteless and free from unpleasant effect after ingestion.

(1) EXTRACT OF BEEF; AND (2) FLUID BEEF.

(LIPTON'S, LTD., CITY-ROAD, E.C.)

The difference in composition between these two excellent preparations will be seen from the following results of analysis: extract of beef: moisture, 18·64 per cent.; organic matters, 61·38 per cent.; and salts, 19·98 per cent. The organic matters presented the following composition: peptone, &c., 30·27 per cent.; albumins, 1·00 per cent.; and extractives, 30·11 per cent. The preparation is obviously highly concentrated and is according to these results a powerful nutrient as well as stimulant. The nourishing constituents occur in practically the same proportion as the stimulating beef extractives. The flavour is pleasantly beefy but somewhat excessively spicy. It is evidently concentrated with care, for there was no indication of burnt flavour. The fluid beef gave the following results: moisture, 42·91 per cent.; organic matter, 40·83 per cent.; and salts, 16·26 per cent. The organic matter contained albumin and fibrin, 6·87 per cent.; peptones, &c., 15·26 per cent.; and beef extractives, 18·70 per cent. The preparation affords a pleasant and satisfactory beef-tea including the albumin and tissue of muscle. According to analysis it contains all that is necessary to sustain the vital processes. Both preparations were found to be free from objectionable preservatives.

TOILET, ANTISEPTIC, AND MEDICATED SOAPS.

(EDWARD COOK AND CO., SOAP WORKS, BOW.)

Soap is itself mildly antiseptic, but its value in this direction by the addition of well-known antiseptic agents is decidedly increased so long as they are compatible. This at any rate is the case with the following soaps which we have examined from the above makers: "camphor, rosemary and borax," "compressed coal tar," and "Cambath." The latter is very agreeable to use. Sulphur and glycerine soap is a very useful combination for the skin. Amongst the specimens also was one called "violet savon de luxe," which is a very excellent toilet soap of well-balanced composition and free from alkali, irritants, and resins. Lastly, we have examined a specimen of hygienic tooth soap which appears to be well adapted as a dentifrice. It is cleansing and neutral and contains a mild antiseptic which we had no difficulty in recognising.

INVALID FRUMENTINE.

(WILLIAM HAY, LIMITED, GROSVENOR-STREET FLOUR MILLS, HULL.)

The microscopic examination of this food indicates that a wise selection has been made of the most nourishing portions of cereals in its preparation. It contains an excellent proportion respectively of nitrogenous, carbonaceous, and mineral matters. Moreover, its flavour is particularly satisfactory, being of a rich, nutty, and malty character. It contains a notable proportion of the germ of wheat. An additional advantage from the dietetic point of view consists in the fact that the nutritive constituents occur abundantly in a soluble condition. The preparation is a decided advance on many farinaceous compounds which at their best consist merely of highly-baked flour.

MEAT AND MALT WINE.

(JOHN RILEY, PENDLETON, MANCHESTER.)

The examination of this wine gave the following results: total solid matters, 11·72 per cent.; mineral matter (containing phosphates), 0 53 per cent.; alcohol, by weight 16 46 per cent., by volume 20 24, equal to proof spirit 35·47 per cent. The amount of nitrogen proved to be 0 167 per cent., which is equal to 8 9 per cent. of albuminoids in the extract. The wine is thus obviously a genuine meat and malt wine, but as we have pointed out before wines of this class possess very little direct nutritive value since the nutrient constituents of beef are not soluble in wine of moderately high alcoholic strength. The wine employed in the present instance is a port of satisfactory character judging from the good flavour of the preparation.

EXTRAIT CANNABIS.

(E. EISSENHARDT, 47, CAMPDEN HOUSE, PEEL-STREET, KENSINGTON, W.)

This preparation of hemp-seed extract would appear to deserve some attention since abroad it is said to have given encouraging results as a nutritive in wasting diseases. It has, in particular, been tried in pulmonary diseases with the result, it is stated, of an increase in the weight of the patient. We have confirmed the analysis published by Dr. Spiegel of the University of Berlin. It consists approximately of one-half starch and one-third albumin, the remainder being made of 8 per cent. of fat, 1 per cent. of mineral matter, and 10 per cent. of moisture. It is prepared for administration by adding a tablespoonful to a pint of fresh milk, which is then boiled until the extract is quite pulpy.

"HIGHLY NOURISHING" STOUT.

(C. VAUX AND SONS, CASTLE-STREET, SUNDERLAND.)

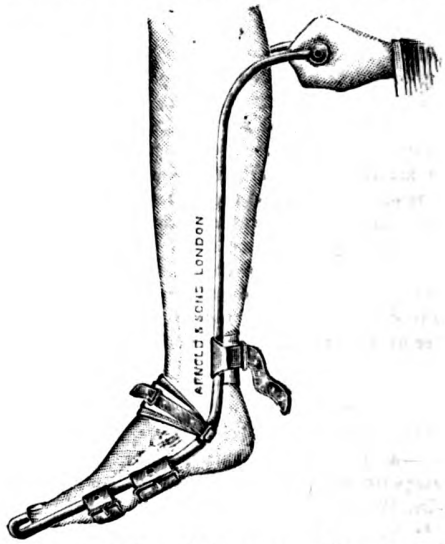
In the brewing of this stout it is said that by paying greater attention to the operation of mashing an increased proportion of nutritive substances appears in the wort and hence in the stout. The results of our examination confirmed this statement. At the same time the stout is free from acidity and is yet of a ripe character. The extract amounted to 8·02 per cent. and the mineral matter to 0·33 per cent. On distillation the stout proved to contain 5 25 per cent. by weight of alcohol or 6·55 per cent. by volume, equal to 11·49 per cent. of proof spirit. As is well known, stout appears to be easier of digestion than beer, and doubtless in the present case this is particularly so, since the digestive action of malt has been pushed in the process of production to a maximum degree.

HYDROBROMATE CACHETS.

FLETCHER, FLETCHER, AND CO., HOLLOWAY, N.)

The value of the hydrobromate combinations of quinine and iron is now well recognised. Recently they have been prepared in a new form for administration which offers decided advantages. This new form is the cachet, which contains a greenish powder soluble in water, forming a pale green solution. On examination this solution is found to contain the iron in the unoxidised condition—that is, as ferrous bromide. Each cachet contains two grains of hydrobromate of iron and one grain of hydrobromate of quinine. We have examined also a cachet containing in addition $\frac{1}{64}$ gr. strychnine. The cachets obviate the drawbacks to the administration of hydrobromates in liquid form, while quinine and iron thus combined do not give rise to cinchonism or gastric disturbance as with ordinary preparations of iron and quinine.

"RISO" SELF-RAISING FLOUR.



(HENRY ROBERTS AND SON, ALUN FLOUR MILLS, MOLD.)

We have examined this flour analytically and practically. It is a flour of excellent quality which yields a small quantity of gas on moistening and heating. It is free from alum. In practice its raising power is not so brisk as it might be, the bread produced being somewhat heavy and yellowish in colour. It is decidedly better for making cakes.

New Inventions

APPARATUS FOR THE TREATMENT OF TALIPES.

NEGLECTED cases of talipes may in course of time undergo so much consolidation and fixation as to be hardly capable of replacement in the natural position by means of the ordinary forms of orthopædic apparatus, and I have found the wrench which is shown in the accompanying illustration to be of

considerable service in suitable cases. The wrench is made in two forms; the principle is the same in both, the essential difference being that modifications are introduced to adapt the one for the treatment of obstinate talipes equinus, while the other is similarly applicable to talipes varus. Messrs. Arnold and Sons, Smithfield, E C., are the makers.

Mandeville-place, Manchester-square, W. HENRY F. BAKER.

A NEW GLASS TANK FOR SURGICAL DRESSINGS.

THESE tanks, a specimen of which is shown in the accompanying illustration, are made of glass and have a tightly fitting metal lid. They are of the same diameter at the mouth as at the base, and being transparent it is possible at a glance to see if stock is getting low. They are made in different sizes, a most useful one being 8 in. by 6 in. by 4 in. which is sold for half-a-crown. The manufacturers are Messrs. Reynolds and Branson of Leeds.

THE LANCET.

LONDON: SATURDAY, MAY 21, 1898.

THE unexpectedly early conclusion of the second reading stage of the Vaccination Bill and its reference to the Grand Committee on Law bring it to the crucial part of its passage through Parliament. If it is to be seriously added to or amended the work must be done by this committee, as the report stage is not likely to see the introduction of any important changes, the power of the Government both in the House of Commons and the House of Lords being practically supreme. If Mr. CHAPLIN has been taking note of the views of the medical profession on the Bill he cannot but have been struck by the fact that divergence of opinion has been comparatively trifling and has referred mainly to less important points, while as to essential principles there has been a very near approach to unanimity. On one question there is, we venture to say, such a consensus of view as is rarely to be found in a profession numbering thirty thousand members proverbially alleged to be apt to differ. That question is the inclusion in the Bill of a provision for revaccination. The Epidemiological Society, the British Medical Association, and the Jenner Society have alike given prominence to this requirement. Even more notable perhaps is the action of the medical officers of health. In face of the continually repeated asseverations by anti-vaccinationists that sanitation without vaccination is capable of preventing small-pox it is a significant fact that the body of men whose special work it is to develop sanitation and whose interests are bound up in the public recognition of the value of sanitation have publicly confessed that the only effective means of preventing and controlling small-pox consists not in sanitation, but in vaccination and revaccination systematically performed. This declaration was signed by some 1100 or more medical officers of health before any Bill was brought forward, and now in presence of the Bill the council of the Incorporated Society of Medical Officers of Health has memorialised the Government regarding these and other points and has offered to send a deputation to Mr. CHAPLIN to support their views.

It seems to us that Mr. CHAPLIN and the Government will be incurring a very serious responsibility if they give no heed to this great body of skilled opinion on the subject of their present legislation. The conclusions at which the medical profession have arrived are based not on *a priori* considerations but on abundant and world-wide experience. The great national experiment which has been carried on in Germany for nearly a quarter of a century has demonstrated the fact that a State can control small-pox by means of vaccination and revaccination even if it be surrounded by other States which are more or less neglectful of the Jennerian prophylaxis and as a result are continually introducing the variolous infection within the German boundaries. In our own country, on a much smaller scale, similar experiments are being constantly made with a similar result. In the postal and constabulary services whenever a local epidemic of small-pox takes place evidence is furnished that these bodies of men specially exposed to infection are yet specially protected from infection and the only adequate explanation of their differentiation from the rest of the population is to be found in their systematic revaccination. In large workshops, with many employés, revaccination at once shows its power in stopping an outbreak, as it did in the Bewsey Ironworks at Warrington.[1] In the Army and Navy, in spite of the comparatively low standard of operative success attained there, an enormous diminution in small-pox prevalence has followed the general use of revaccination, and in our small-pox hospitals the revaccinated nurses dwell and work unharmed in the midst of a living fire of variolous infection.

While we refer to the example of Germany it is to be clearly understood that we do so with a difference. In Germany there is systematic vaccination and revaccination and there is also strong compulsion with regard to vaccination and revaccination. As a profession it is our duty to tell the State how it may prevent and control small-pox; but assuming that the State accepts our teaching as to the value of the preventive means it is then primarily the duty of the State itself to decide how the prophylaxis which we advocate and which the State adopts shall be applied. The Legislature must look not merely to the value of vaccination but to the condition of public feeling on the subject and to the principles which guide the making of laws in a democratic country. Every individual in the realm ought to be vaccinated and revaccinated and the State should provide the means and should use all reasonable legislative pressure and influence towards this being done, but how far it should resort to actual compulsion or physical force is a question in which medical men are interested rather as units in the body politic than as a profession. Our position, therefore, is this, and we hold it to be unassailable, that primary vaccination and revaccination being both necessary for the prevention of small-pox, both alike ought to be legislated for, and that it will be a huge blunder on the part of any Government to make a new vaccination law and to omit from it all provision for the systematic maintenance and encouragement of national revaccination.

THE recent action of the General Medical Council in regard to the employment of unqualified assistants will probably be challenged at the approaching meeting. It is not likely to be seriously modified in the sense of giving a new lease to the old practice of doing a great part of the work of medical practice with the help of unqualified assistants. There, doubtless, is a proportion of unqualified assistants who have practically completed their curriculum and whose

[1] See Dr. Savill's Report to the Royal Commission on the Warrington Epidemic.

non-qualification is an accident or a misfortune for which they are to be sincerely pitied. And possibly the General Medical Council may consider that their case is entitled to some special consideration at the hands of the medical authorities. Be this as it may, t is evident that in the future much of the work now, or till lately, done by unqualified assistants will have to be done by men recently qualified. It is of great moment under these circumstances that these men should be encouraged and advised by their teachers to take an opportunity of seeing all they can of private practice during their curriculum. There is undoubtedly something in the complaint of general practitioners who employ assistants that the unqualified assistant is more useful to them than the qualified. This remark is made too frequently and with too much obvious feeling to be altogether disregarded. It is too apparent to be disputed. The unqualified assistant has been in private practice nearly all his days and it has been a kind of education to him. He has probably seen every variety of it—the good practice, the cheap practice, the branch practice, and the practice with innumerable clubs attached to it. He is familiar with dispensing and the ready use of ordinary drugs and their doses, perhaps too familiar. The common diseases are easily recognised by him. He has besides, and not altogether to his discredit, if not an interest in the business aspect of practice, no aversion to it or to taking his fair share in the attention which it requires. All this will have to be recognised by the qualified men who are to do the work of the present unqualified assistants and should be recognised by their teachers. If it is not so recognised much inconvenience will be felt in the near future by a very large class of practitioners who have to conduct practice on a large scale for small rates of remuneration or over awkward areas of country.

The General Medical Council has already to some extent recognised the importance of this element in medical education. Soon after the introduction of Direct Representatives into the Council by the Act of 1886 the defects of the curriculum in this respect were pointed out, chiefly by the Direct Representatives themselves. They showed that in the examinations at least there was a conspicuous absence of tests of the knowledge of common diseases, and they were well supported in this course by such men as the late Sir WILLIAM GULL, Sir SAMUEL WILKS (then Dr. WILKS), and others. It was natural that the Direct Representatives should insist on such defects in medical education, as they represented so largely the general practitioners of the country as distinguished from its consultants. The Council adopted their views but with a certain reluctance. The Council is made up predominantly of medical teachers or the representatives of teaching and examining bodies. They understand little of education apart from a medical school or a large hospital—perhaps naturally so. And though they conceded in their regulations that six months of the last year of study might be spent in pupilage to a practitioner they have never insisted that such a pupilage should be compulsory. Fortunately the late Notice concerning the employment of assistants recognises this regulation of the General Medical Council and does "not apply so as to restrict the proper training and instruction of *bonâ-fide* medical students as pupils."

One way out of the difficulty in which busy practitioners find themselves, owing to their being deprived suddenly of the power to employ unqualified assistants, is to encourage this education in general practice which was contemplated by those who urged the Council to require some time to be spent under the supervision of a practitioner who had the means of teaching. The Council can do much in this way to mitigate the inconvenience which it is alleged has been caused by the recent Notice and which otherwise is likely to extend over several years. Some would go so far as to insist on such an education in practice being required from every man before he becomes qualified, but we question if such compulsion is altogether advisable, although much may be said for it. It has drawbacks as well as advantages. The old race of practitioners had very little other education, and among the eminent leaders of the profession now living there are few into whose education such an element did not enter and who would not now maintain that it was one of the most valuable parts of their training. The education of lawyers has been almost entirely, and is still largely, the mere education of practice and constant contact with legal work and cases. No doubt in their profession the systematic teaching of law and the principles of law has been defective and needs to be improved, but in medical education it is the reverse. We could do with a little more contact with cases in their every-day occurrence and aspect; and it is not improbable that one result of the recent action of the General Medical Council will be to provide a remedy for this very defect. The Council is not a mere academic body. As a Council it has none of the exclusive interests of a mere examining body or a teaching body or, as in the case of a university, of both. It has to recognise the great business of medical practice in every part of the country and in every kind of population and to train a profession familiar with disease in its practical points and capable of rendering to those who suffer from it ready and effective help.

ATTENTIVE readers of the medical journals may make a pretty good forecast of the nature of the business which is likely to occupy the time of the General Medical Council when it holds its sixty-fifth session, which will commence on Tuesday next at 2 o'clock, especially if they also study the Council's minutes and those of its Executive Committee. A recent communication seems to show—for we have not yet all the facts before us—the chance of a somewhat sharp passage of arms between Mr. VICTOR HORSLEY and the new President as to the right of members of the Council to have access to the documents and records of the Council whenever they please. Both are strong men, having had considerable experience of business as well as of science, and both must be credited with jealousy for the reputation of the Council as a business body as well as one representative of the most liberal of the professions. The question raised by Mr. HORSLEY is very important and seems to us to be very easy of solution. The difficulty

will be to ascertain how it is that so simple a question can be a cause of heat or friction between two members of the Council who are so distinguished and who might be thought capable of settling much more difficult ones with ease.

To pass to other and more agreeable matters, there are two subjects on which the Council will not have much more to say at this or, we trust, any subsequent meeting and in regard to which it may fairly be congratulated on its action. We refer to the question of foreign practitioners, largely English, practising in Italy, and the subject of the true principles that should be the basis of any legislation on the subject of midwives. We mention these subjects here only to offer our own acknowledgment of the good work done by the Council. The representations of the Council supported by the Foreign Secretary have sufficed to elicit from the Government of Italy the declaration that it is no longer their intention to legislate in a sense unfriendly to those practising in Italy without the sanction of Italian degrees. The effective action of the Council in arresting, by its representations to the Government, the progress of the Midwives Registration Bill, which would have left the Gamps very much where they are and which, moreover, had the almost unanimous disapproval of the medical profession, is a matter of too recent history to need further mention here.

The question of defects in preliminary education is likely to be again brought before the Council in two ways. The Chairman of the Examination Committee is expected to give the results of a correspondence with the Director of the Medical Department of the Army, who in his last valuable returns expressed himself unable to give the Council information as to the Preliminary Examining Body which had passed candidates showing great deficiency in general education. It is greatly to be regretted that he could not give the information asked for, for this is one of the chief means by which the Council can identify the bodies whose examinations are faulty and it is hoped that Sir DYCE DUCKWORTH will be able to induce the Director of the Army Medical Department to afford similar information to that which the Director of the Navy Medical Department supplies. But the question of the efficiency of the preliminary examinations recognised by the Council will be raised in a broader and more searching manner. It is understood that the College of Preceptors feel aggrieved at the reflection thrown on the examination for their second-class certificate and that the whole question of the standard of this examination, as compared with other examinations of a similar standard which are still recognised, will be raised. Our readers will remember that the members of the Council seemed to doubt whether they were not acting in a halting way in the somewhat timid course which they took. The subject will doubtless be further elucidated at the approaching meeting.

Another question of interest which may be expected to be raised again is that of the extinction of the class of unqualified assistants, but this very important matter is treated in another column. It is to be hoped that the President of the Council will be able to give some good account of his action in the way of securing an interview with the President of the Local Government Board concerning the very loose manner in which death or burial certificates can be obtained.

The question of the Disciplinary Powers of the examining bodies is emphasised every day by one case or another and it will be disappointing if some progress is not reported on the part of these bodies. They cannot be too often reminded that they owe to their diplomates the friendly correction of errors of conduct at an early stage when a word of suggestion would avert greater errors which bring men under the risk of being charged with infamous conduct in a professional respect. Apart from the actual programme of business, which, of course, we have not seen, there are other subjects of great interest, the further discussion of which may be expected, including Mr. THALE'S views of excessive and superfluous examinations. We have said nothing of Penal cases, but we have said enough to show that the Council has work to do which will require its careful consideration and the best use of its time.

Annotations.

"Ne quid nimis."

THE PASSING OF A GREAT MAN.

WE do not intend to give any detailed obituary notice of the great man who has just passed from among us. Our readers have before them the ample story of Mr. Gladstone's grand career in all the daily papers and in most cases it will be the province of such papers to discuss political matters upon which we are unable as a medical journal to take a view. But at the same time we desire to register our feelings of profound admiration for the dead statesman's lofty ideals, unrivalled intellectual powers, and wonderfully sweet and buoyant temperament. In Mr. Gladstone a lowly trust in God was joined to the highest aspirations for the good of humanity, and the sense of the loss which the nation feels itself to have sustained by his death cannot be adequately expressed. Medicine, its science and practice, falls as a part of the social scheme beneath the domination of a real national leader, so that in common with the rest of the community we rejoice when our leader is a good man as well as a great one, and while rejoicing benefit. It is unnecessary to point to special acts or speeches that we may prove Mr. Gladstone to have been the friend of those who follow our calling, though to do so would be easy. Being the man that he was it was inevitable that he should sympathise with us and with all who work to help the weak. For Mr. Gladstone was exactly "the man of mercy" whom the Son of Sirach has described, as he was and is, also, one "whose glory shall not be blotted out" but "whose name liveth to all generations."

"THE LIMITS OF PROFESSIONAL SECRECY."

MR. E. A. BARTON, in a letter under this title in our issue of May 7th stated a situation which has often caused difficulty to medical men, who will be grateful to him for having ventilated the subject. We are of opinion that in a general sense, if a medical practitioner is engaged by an employer to professionally attend an employé he ought not to divulge to such employer the nature of the illness of the patient. Of course he should exercise his discretion in the matter. There could be no harm done if the illness were of a

simple nature—simple, that is to say, as regards its bearings beyond its medical aspect. We can imagine circumstances which might render it wise and obligatory on the medical practitioner to inform the employer of the nature of the servant's ailment—e.g., in a case of infectious disease. We do not think an employé would recover damages from a medical man for making known this complaint, provided always that the facts could be substantiated and that they were communicated without malice. There could not be a valid contract between the employer (who pays for) and the attending practitioner except as to attendance and remuneration. It is no part of a medical man's duty to act as a secret police agent. We should advise him to inform the employer that he should consider any information he might obtain in his professional capacity as strictly private between himself and the patient and not to be divulged except with the free consent of the latter. We consider that secondary syphilis, for the purposes of the argument, should be classed as an "infectious disease," since through ignorance, negligence, or inadvertence it might be conveyed to other members of the household. Pregnancy or disease arising from alcoholism ought not to be divulged to the employer without the consent of the servant.

THE QUEEN'S VISIT TO NETLEY.

ON Saturday, May 14th, the Queen paid a second visit to the Royal Victoria Hospital, Netley, to inspect the invalids who have lately returned from the North-west frontier of India, to offer her sympathy to those who have lost health or been wounded in support of the nation's weal, and to decorate with the highest national reward those in hospital whose valour has of late been so conspicuous. Accompanied by Princess Christian, Princess Henry of Battenberg, and Princess Victoria of Schleswig-Holstein, and attended by the Duchess of Roxburghe, Major-General Sir John M'Neill, Major the Hon. H. C. Legge, and Lieutenant Ponsonby, Her Majesty travelled from Windsor *vid* the Great Western and South-Western lines, and after a run of two hours arrived at the Netley station at half-past four o'clock. The afternoon was magnificent, the sun shining brilliantly. At the station the Queen was received by General Davis (commanding the Southern District), by Colonel Creagh (A.A.G. at Netley), and Major Sumner, A.D.C. The Earl of Northbrook (Lord-Lieutenant of the county) was also present, accompanied by his daughter, Lady Emma Crichton, and her husband, Brigadier-General the Hon. Henry Crichton, commanding the Portsmouth Brigade of Volunteers. The boys of the training ship *Mercury* formed a guard of honour at the station and as the Royal carriage passed Her Majesty was saluted and the band played the National Anthem. The road from the station to the hospital was densely packed with spectators and the Queen received an enthusiastic greeting. Her Majesty arrived at the entrance to the hospital at ten minutes to five o'clock and was there joined by Prince Maurice of Battenberg who had been driven over from Lyndhurst with his tutor. The guard of honour at the hospital was supplied by the East Lancashire Regiment, whilst the Northumberland Fusiliers kept order in the grounds. Under the portico the Queen was received by Surgeon-Major-General Nash, P.M.O. of Netley, and presented with a beautiful bouquet by Miss Stevenson, the daughter of Surgeon-Colonel W. F. Stevenson, Professor of Surgery in the Army Medical School. The following officers were presented to the Queen by Surgeon-Major-General Nash: Surgeon-Colonel J. Lane Notter (Professor of Hygiene), Surgeon-Colonel W. F. Stevenson (Professor of Surgery), Surgeon-Colonel K. Macleod (Professor of Medicine), Brigade-Surgeon-Lieutenant-Colonel Blennerhassett, C.M.G., Brigade-Surgeon-Lieutenant-Colonel W. E. Webb, Surgeon-Lieutenant-Colonel W. L. Chester and Surgeon-Major W. Dick. Miss Norman, lady superintendent of nurses, was also introduced to the Queen, who proceeded in her chair along the lower corridor, passing a file of convalescents, to the lift, by which she was conveyed to the surgical division of the hospital. Here the Royal party visited the bedsides of the wounded, Her Majesty speaking words of kindly sympathy to every patient. The Queen went into nearly all the wards. In the corridor Piper Findlater of the Gordon Highlanders and Private Vickery of the Dorset Regiment were stationed; they were presented to Her Majesty and the impressive ceremony of pinning the Victoria Cross on the left breast of each was accomplished, the Queen commending them for their bravery and congratulating them on attaining the highest honour a British soldier can have conferred upon him. The tour of the surgical division over, the Royal party visited the medical division, the Queen seeing during her whole inspection nearly 900 patients. When Her Majesty again reached the lower corridors Lieutenant Pears of the Cameronians was presented to her, he being one of the officers who was wounded on the frontier; he has been under treatment for some weeks in the hospital for a bullet wound of the leg. It had been arranged that Her Majesty should leave Netley at half-past five o'clock, but at that hour the Queen had not completed her visit, and so as not to disappoint any patient she gave directions that the journey should be postponed for half an hour, by which time she had succeeded in accomplishing her mission of sympathy. At six o'clock the Queen entered her carriage, but before doing so she expressed to Surgeon-Major-General Nash her great satisfaction at all she had seen and with all the arrangements made for her. While Her Majesty was passing along the lower corridor Piper Findlater played "Haughs of Cromdale" on the pipes which have lately been presented to him. The Queen was looking exceedingly well and on emerging from the hospital showed considerably less fatigue than on the occasion of her former visit; she was enthusiastically cheered on leaving the hospital and all along the road to the South-Western railway-station.

TWICKENHAM AS A HEALTH-RESORT

A CORRESPONDENT writes: "Recently the contractor to the Twickenham Urban District Council for the removal of house refuse deposited many cartloads of the contents of 'dust'-bins on a piece of ground (which is being rapidly covered with houses) within 20 yards of the windows of my dwelling-house, and I called the attention of the medical officer of health and of the inspector of nuisances to the deposit and asked for an immediate removal of the nuisance created. An inspection of the filth revealed the usual contents of 'dust'-bins—decaying vegetation, fish offal, empty tins, bones, scrapings, &c.—and the stink from it was already plainly noticeable in my house. The medical officer replied stating that he had drawn the attention of the contractor to the nuisance and had instructed the inspector of nuisances to visit and report should any nuisance exist in the future. A few shovelfuls of earth—not sufficient to cover it up—were thrown on the filth, and I, not thinking this a sufficient 'abatement' of the nuisance, wrote again to the medical officer of health and urged him to order its complete removal. To this the officer replied stating that there was 'just cause for complaint' and that the contractor had 'undertaken to cover up with soil to the depth of 15 or 18 inches the whole of the refuse which had been shot at this spot, and that no more shall be shot there.' This covering up (which has not been done) I did not and do not deem satisfactory, and accordingly, under Section 106 of the Public Health Act, I asked the Local Government Board to order the removal of the filth. The receipt of my letter was duly acknowledged the next day, and a further communication was received seven days after, saying that the

Local Government Board had no power to interfere in the matter. I then went to the offices of the Local Government Board and was courteously received by one of the officials, who explained that although the Board had the power to interfere they never exercised that power and would not do so in particular cases: they would only do so where a sanitary authority generally neglected its duty. If the Board were to act in individual cases the staff of officials would require to be largely augmented. The Board could therefore only recommend me to apply to a magistrate to order the removal of the filth. I may mention that last summer a much larger quantity of house refuse was deposited on land in the street on the left hand side of me, with the result that, in addition to the stink arising, the whole neighbourhood was pestered with a plague of flies for many weeks. This same land is now covered with a front row of houses and more are being built!" Our correspondent now asks us to give him our opinion of the matter. If the facts are correctly stated by him we have no hesitation in saying that a serious breakdown in local government is revealed in this small matter. Firstly, the urban district council should know better than to dump stinking refuse within nose-range of the ratepayers. Secondly, it is illegal to build immediately upon such "foundations," and a watchful eye should be kept upon those responsible for the building operations now proceeding to see that they do not transgress the law. Thirdly, a covering of 18 in. of earth is not, when it is put there, a drastic measure for the abatement of the nuisance, though it would undoubtedly have a great remedying effect. As, however, we learn from our correspondent that eighteen days after the contractor had undertaken to cover up the filth masses of it still remained exposed, it is clear that the method of abatement has not received due trial. Fourthly, why did it take a week for the Local Government Board to find out that they had no powers—or, rather, no powers that they intended to exercise? Our recommendation to our correspondent is that he should take competent and unbiassed witnesses to the spot to support his statements if necessary and that he should apply to a magistrate for an order compelling the urban district council's contractor to remove the filth. This measure would possibly give more trouble than covering the mass over with soil, but we are certain that the able medical officer of health will agree with us that it is a surer method of abatement, while the fact that the contractor failed to do for so many days what he had undertaken to do encourages us in the view that if he is given a little trouble now it will do him no harm in the future. For he has certainly entailed much trouble on a fellow citizen. The story is not a good advertisement for the neighbourhood. If houses are being built at Twickenham on such foundations as our correspondent indicates, and if any inhabitant of Twickenham may wake up and find that the contents of other persons' ashpits, scullery pails, and middens have been added to his frontage, Twickenham will soon be known as a suburb to be severely avoided.

THE SMOKE NUISANCE: AN INTOLERABLE STATE OF THINGS.

IT is fortunate for Londoners that the present period of the year happens to be spring and not winter or late autumn, for the Welsh coal strike appears to have given opportunity to hotel and restaurant proprietors and others to commit a serious breach of hygienic law. The appearance of several of the great thoroughfares of the metropolis has for the last few weeks forcibly suggested the "black country." Never was London deluged in blacker smoke on all sides than it has been recently. The Strand in particular, that avenue of cafés, restaurants, and hotels, is a disgrace as it is a reproach to the public health authorities concerned. For the last few weeks this thoroughfare has been bathed in murk and gloom and the atmosphere has been offensive with sulphurous emanations and irritating smuts. The nuisance continues at the time of writing with unabated vigour and we possess a carefully kept record of the foul vomiting of several chimneys in the immediate vicinity of the offices of THE LANCET. It goes on, not for minutes, but for hours, and is not only a nuisance to health, but a source of considerable injury to property. The effect on buildings decorated with light colouring is disastrous and the paint everywhere rapidly assumes a deteriorated appearance. All endeavours to keep windows clean are utterly futile. And to open them is only to invite layer upon layer of soot to cover our books, papers, and manuscripts. Even at Westminster they have noticed it, for in answer to a question put by Mr. Labouchere in the House of Commons last week it was stated that the matter was one with which it was the business of the County Council to deal. The plea that the nuisance is caused through the difficulty of getting Welsh or comparatively smokeless coal is idle. The smokiest coal can be burnt without evolving dense or almost solid smoke by the adaptation of a suitable and simple smoke-consuming contrivance above the furnace. It is certain that if the meteorological conditions of winter had prevailed the smoke would have been locked in by particles of moisture and the worst possible kind of fog would have hung over the metropolis. It is the duty of the London County Council to set in motion the powers vested in them under the Public Health Act, containing, as it does, a clause which runs as follows: "Any chimney (not being the chimney of a private dwelling-house) sending forth black smoke *in such quantity* [the italics are ours] as to be a nuisance shall be deemed to be a nuisance liable to be dealt with summarily in a manner provided by this Act." Then why are the offenders not "dealt with summarily"? Since the above was written we are glad to record that as a result of the representations of many solicitors and others in Lincoln's Inn-fields proceedings were taken on the 18th inst. against the Metropolitan Electric Supply Company for having on twenty days allowed the chimneys of their works to emit black smoke in such quantities as to constitute a public nuisance. An order for the abatement of the nuisance was made by consent with £5 5*s*. costs on the first summons and 6*s*. on each of the nineteen others. We trust that this will lead to the suppression of the nuisance which continues to exist in a great many other places.

HOSPITAL ACCOMMODATION ON BOARD PASSENGER VESSELS.

THE rapid growth of public opinion in relation to matters sanitary, together with the increasing number of persons who for one or another reason "go down to the sea in ships," cannot fail to attract more and more attention to the sanitary condition under which the floating population lives. A considerable number of our port sanitary authorities have within recent years done excellent work in this direction, though there are, we regret to say, still some who have contributed next to nothing towards the general well-being of the sailor's existence. In matters of construction, however, the powers of port sanitary authorities are somewhat limited, and a badly arranged vessel is not likely in practice to be much modified by any powers which they possess. In a word there is at present no proper guarantee that a vessel will be constructed with due regard to the health and comfort of those who may from time to time occupy her. What we really need, but are not likely at present to obtain, is that

the plans of proposed vessels shall be submitted to some authority or authorities capable of advising, and to a certain extent of insisting, upon adequate ventilation, drainage, and cleansing arrangements together with a proper provision of hospital and lavatory accommodation. Pending the advent of this machinery port medical officers of health may exercise no little influence on the construction of ships in the future by drawing public attention to the bad arrangements obtaining on existing vessels and pointing out how such defects may be obviated. We are glad to see that Mr. Wellesley Harris, the medical officer of health of the borough and port of Southampton, has taken this view of the situation and that in his current report he gives an account of the hospital accommodation of 23 passenger vessels frequenting that port. Neither the names nor the tonnage of the vessels in question are furnished, but having regard to the fact that not a few of the finest liners afloat arrive and depart from Southampton we may reasonably conclude that Mr. Harris's observations have reference to some of the largest shipping companies in existence. The results of the inspection are arranged in tabular form in the report, and it is at once apparent that much reform is needed; for instance, in a vessel carrying no less than 1230 of passengers and crew there is but *one* hospital with five beds, and although in relation to the total number of persons carried this gives one hospital bed to 246 persons, it is clear that in actual practice, there being no separate accommodation for each sex, or presumably for the crew, nothing approaching this ratio really obtains. We are told, too, that the door of the hospital opens into the third-class dining saloon and that there is a water-closet in the hospital separated from the rest of the interior by a wooden partition. Clearly, as Mr. Harris remarks, this hospital is useless as a means of isolation. There are several other vessels on the list to which comments similar to the foregoing would apply, but on the other hand we note five vessels, carrying, all told, from 940 to 1450 persons each, where the hospitals are regarded as "very satisfactory for all purposes." In summing up the hospital question Mr. Harris thinks that much reform is necessary as regards the situation, cubic capacity and ventilation, and the proportion of baths to crew and passengers. He thinks that well aft on the poop deck is the best place for ships' hospitals, and in large passenger liners, despite the proximity of the propeller and the range of motion there experienced, this view is on the whole a sound one. Of course, the main issue from the view-point of preventive medicine is that the hospital, which perhaps as a rule is used for non-infectious cases, can be used with safety for infectious diseases when necessary; but at the same time we must have due regard to the comfort of the invalids and to the accessibility of the hospital during monsoons, &c. Mr. Harris has done well to draw attention in his report to hospital accommodation afloat, and although the public can hardly be expected to render much assistance they may bring into operation the laws of supply and demand by showing a preference for such vessels as are properly equipped in this particular.

SEDENTARY EMPLOYMENTS.

VERY little observation will suffice to convince anyone of the difference which exists between those who follow sedentary, and those engaged in outdoor, occupations as far as their physical appearance goes. The city clerk, the employés in shops, and those who follow sedentary occupations, whether male or female, do not usually present anything like the healthy appearance, nor have they the colouring, the healthy facial expression, or the robust aspect and upstanding carriage, of those who live in the country or at the seaside, or of those who follow an out-of-doors life and take sufficient physical exercise. But making every allowance for the depressing effect of sedentary habits and occupations in these respects how much of it is avoidable and attributable to the unhygienic conditions, personal and otherwise, under which such occupations are carried on? It will be frequently found that the offices, rooms, and places of business in which clerks and others are employed for the greater part of the day are small, badly lighted, ventilated, and warmed, that the air is more or less stagnant and foul owing to complicated or bad structural arrangements, with probably narrow, tortuous, dark passages, that the water-closets are improperly placed, and that a good deal of overcrowding exists. Now although a sedentary life is not, of course, the healthiest kind of life it is nevertheless more or less healthy in proportion as the local conditions are healthy or otherwise. Clerks and city employés are not generally robust folk, they usually possess a feeble circulation, their work is nerve-exhausting, entailing as it does various degrees of mental tension and strain of eyesight, and sedentary work is, moreover, cold work. Those employed are liable from the nature of their duties and the closeness of the atmosphere in which they have to pursue them to headaches and a feeling of exhaustion which probably induces many of them to have recourse to "nips" of alcohol. The necessary remedies obviously are fresh air and light, together with warmth; the incoming air requires to be warmed during the greater part of the year in this climate. Business people in the city, even to put the matter on merely economical grounds, do not practically get the best attainable out of those in their employ for want of proper care and attention to these details, to say nothing of the inconvenience and pecuniary loss arising from frequent absences from temporary causes of ill health. Great improvement has no doubt taken place of late years and most of the banks and large city offices are well provided in these respects, but there still remains much to be done which could be effected if enlightened views about the laws of health and hygiene were more generally recognised than they are.

THE POSITION OF THE HOSPITAL MEDICAL OFFICER AS WITNESS AT AN INQUEST.

AT an inquest held recently at Lowestoft on the body of a man who died in the hospital there, Mr. H. Bournes Walker, one of the honorary surgeons to the institution, was called to give evidence as to the cause of death. Before doing so he said that he was bound to make some remark as to the conditions under which he had been summoned there that day. This was the fourth time upon which he had been called as a medical man to give expert evidence as to the cause of death and had received no fee whatever. That fee was refused on the ground that he was a hospital surgeon and he thought it was manifestly unfair that because he gave his services to a charitable institution the Crown should demand his attendance at an inquest without fee. His duty consisted in treating patients, but when death unfortunately ensued he considered that his duty ceased. He had nothing to do with a patient after he had died in the institution. But the Crown stepped in and said that he must perform certain duties. He had performed a very fatiguing and unpleasant necropsy by order of the coroner, a task which had engaged his attention for no less than four hours, and now he had to give expert evidence. He thought it only fair to himself and his colleagues to protest against being compelled to give expert evidence without receiving any fee. The coroner (Mr. C. W. Chaston) thought the protest had been rightly made. He fully sympathised with Mr. Walker, and he thought the law, as it applied to the case under notice, was

wrong. He very much doubted when the Act was made if it was intended to prevent a fee being paid to a medical witness in such cases. But the county council were not to blame in the matter. He had consulted their deputy clerk and learned that their feelings were in accord with his own, but he regretted that in the present state of the law no fee could be paid. There was a time when some coroners did pay and he himself had stretched a point, but if he were to pay now the Government auditor would surcharge him. He had, however, communicated with Mr. H. S. Foster, M.P., and the matter had been debated by the council of the Coroners' Society, who said that it was an injustice and thought that some steps should be taken to get the law altered. But why did not the medical men go to their own strong society to get the law altered? He himself should be very glad to see a fee paid in such cases. Mr. Walker thanked the coroner for his expression of opinion, and we take the opportunity, in behalf of hospital officers, of doing the same. We are not prepared to say flatly that all hospital medical officers should always be paid for all evidence at all inquests, but it is certain that discretion in the matter should be vested in the coroner.

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

THERE proved to be a wealth of subject at the disposal of the speakers on the occasion of the annual dinner of this society, which took place at the Hotel Cecil on Tuesday, May 17th. The Pharmacy Acts Amendment Bill was discussed, the New Pharmacopœia was a common topic at the table, a code of ethics was enthusiastically upheld, quackery and delusive and subtle advertisements were denounced, and lastly an interesting reference was made to liquefied hydrogen by Professor Dewar, who has recently achieved this result in a practical manner. Professor Dewar, in reply to the somewhat comprehensive toast "Science," referred to the close relationship of chemistry to pharmacy and to the excellent and original research which many pharmacists had taken up with results of far-reaching interest and importance to chemical science. He would be sorry to say how much the work of investigation at the Royal Institution had cost, but it had largely been defrayed by the contributions of friendly men of science and probably in no other country would the work have been possible without Government aid. The Hon. W. F. D. Smith, in responding to "The Houses of Parliament," complained of the pressure of public business which had largely militated against the Pharmacy Acts Amendment Bill, of which he was the introducer, receiving the consideration which it deserved. There was little chance, he feared, of a new measure being passed this session. In the meantime the matter should be strongly urged upon the notice of Ministers and no time should be lost on the part of pharmacists themselves to put forward the strongest possible representations in favour of amendment. Mr. G. T. W. Newsholme (Vice-president), in giving the toast, "The Medical Profession," expressed approval of the action of the General Medical Council in the steps which they had taken to improve the status of the profession and the placing of restrictions upon unqualified men; he wished a similar course could be more severely adopted in the pharmaceutical profession. In reply to this toast Sir Walter Foster said that the medical profession owed much to pharmacists. They had given invaluable assistance towards the completion of a new Pharmacopœia which was a national work. He trusted that the Pharmacopœia would prove a means of eradicating the widely-advertised nonsense about certain drugs and preparations. The public required to be protected against such statements and eventually education, he confidently hoped, would put a stop to all quackery. Mr. Bryant, President of the Royal Medical and Chirurgical Society, with whose name also the toast was coupled, endorsed the previous speaker's remarks and acknowledged the help of the committee of the Pharmaceutical Society and of Dr. Attfield in the accomplishment of the new Pharmacopœia. The toast of "The Society," coupled with the Health of the President, was proposed by Sir J. Crichton Browne and Mr. Walter Hills responded. The company present was a large one and included many representative men of science and medicine. We congratulate the society on its success and on its admirable aims in regard to making the pharmaceutical profession an honourable and dignified one.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT IN SCOTLAND.

THE Secretary of State is now prepared to receive applications for the appointment of medical referee under the Workmen's Compensation Act, 1897, in Scotland. The arrangements adopted for Scotland are the same as those already announced for England and Wales, except that in the distribution of appointments the sheriffdom is substituted for the county-court circuit. The duties and the fees of the referees and the qualifications required from candidates are exactly the same. All applications should be addressed to the Private Secretary, Home Office.

THE RIVER BRENT.

THE Middlesex County Council are promoting a Bill to make more effectual provisions for preventing the pollution and obstruction of the streams of the County of Middlesex and to confer further powers on the County Council of Middlesex for that purpose. This Bill contains sections relating also to the granting of loans to local authorities, to questions concerning main roads, and to other matters with which we are not concerned. The preamble of the Bill states: "Whereas the waters of the Brent and other streams of the County of Middlesex or parts thereof are, especially in dry seasons, so polluted by sewage and otherwise as to cause a nuisance and to endanger the health of the residents in their vicinity," that the Middlesex Council wish to have power to take means to preserve the purity of the water, to dredge the river, to shorten bends, to cut trees which may obstruct navigation, and to place weirs on parts of the river. Certain powers are also asked for in relation to weirs on the Grand Junction Canal and to ensure the purity of the water of the Brent reservoir. It is provided that in case of dispute between the canal companies and the County Council matters shall be settled by arbitration. District councils are to be authorised to contribute towards the expenses of the County Council for the inspection of lands for any purpose connected with carrying out the provisions of the Bill. Power of entry is provided and samples of sewage effluents may be taken. Sanitary authorities are to afford facilities for factories to drain into their sewers. No new sources of sewage pollution are to be allowed and liquid sewage is no longer to be sent into the river or into the streams which feed it. Existing sources of pollution are to be discontinued and provisions are made for enabling the Council to ensure that this is done. Owners are to be served with notices to abate within a reasonable time any nuisance which may exist and the Council are to have power to stop outlets to sewers which at present discharge into the stream or its effluents. Weeds and offensive matters are not to be thrown into the stream. Factories are not to discharge polluted liquids into it. The river must not be dredged without licence from the council nor may the water be abstracted from it. At the present time the supply of water to the Regent's Canal and its collateral cuts are obtained

from a reservoir on the Brent in the parishes of Kingsbury, Willesden, and Hendon. The Brent reservoir was constructed prior to the year 1852 and is maintained under powers of various Acts of Parliament, amongst which there is a local and personal Act of the thirty-third year of George III., chapter 80 (1793). This is the Act which authorised the construction of the Grand Junction Canal. In 1851 an Act called the Regent's Canal Reservoir Act was passed which authorised an enlargement of the Brent reservoir. Under these Acts provision was made for the delivery from time to time into the River Brent of such a quantity of water as should be lost by the construction of the works authorised by these Acts. In the year 1892 the Regent's Canal City and Docks Railway Act was passed and under its provisions the North Metropolitan Railway and Canal Company became owners of the undertaking and proprietors of the Regent's Canal. It is found that the amount of water flowing down the River Brent is materially diminished and that it is insufficient to keep the stream in a cleanly state.

THE CONTROL OF INFECTION AND CONTAGION IN SCHOOLS.

IF every layman were possessed of such medical knowledge as to enable him to recognise the earlier symptoms of infectious disease we should be in a better position to control and to prevent epidemics than we are in at present, but pending the advent of this state of affairs we must perforce do the best we can with the imperfect material at our disposal. If all our school-children could be examined daily by medical men who had had exceptional experience in infectious disease and in diseases of the skin we should be able to reduce the damage done by schools *quâ* infection to a minimum, and it may be that before the next century has far advanced we shall see some such system as this generally in force. Meanwhile we must ask for the assistance of the school teacher and of the parent, and the former of these may render very valuable aid by virtue of the fact that he knows the children and is thus able to detect any marked departure from their normal condition. The teacher must, however, have certain rules to guide him in arriving at a conclusion as to what course he is to take, and it is in this direction that he may well look for the assistance of the medical officer of health. Dr. Meredith Young, the medical officer of health of Crewe, has recently forwarded to us a placard relating to "Particulars of certain Infectious or Contagious Diseases for the Guidance of School Teachers," a copy of which is hung up in each class-room of every school in Crewe. The diseases in question are divided into two classes—*A* and *B*. In the case of *A* all children from the infected house are to be excluded from school; in the case of *B* the exclusion of the actual sufferer is alone insisted upon. In class *A* are scarlet fever, diphtheria, measles, German measles, whooping-cough, chicken-pox, mumps, influenza, and small-pox; in class *B* are erysipelas, ringworm, skin diseases of the head, scabies, and ophthalmia. The placard is divided into three columns. In the first is the name of the disease; in the second are the signs and symptoms of each disease together with the channels by which infection is supposed to be given off; and in the third column is set forth the period for which in each instance the children should be excluded from school. The suggestions are that when the teacher considers as a result of his observations that a child may be suffering from any of the diseases enumerated the child (and in certain cases all the children from the same house) shall be sent home with a note to the parents asking them to have the child examined by a medical man without delay. The parent is also to send word to the teacher as to the result of the medical examination. In the case of scarlet fever, diphtheria, and small-pox the children are not to return until a certificate is received from the medical officer of health, but in the case of all the other diseases the teacher is apparently to exercise his discretion after consulting the memorandum. Apparently in the case of class *A* no discretion is left to the teacher as to sending home the other children from the same house, but it appears to us that it might be well to modify this clause so as not of necessity in a doubtful case to send away all the children in the first instance. There will probably, too, be some difference of opinion amongst medical men as to the inclusion and omission of certain diseases in class *A*; no reference in either class is made to enteric fever. But what in practice the memorandum amounts to is that if a child appears to be ill or presents any eruption or rash he or she should be sent home, and this is no doubt an excellent arrangement. The difficulty will begin when the parent is invited to call in a medical man. Dr. Young casts a wide net in enumerating the channels through which infection may be given off, but it is well to err on the safe side. The memorandum is one of considerable interest both from an academic and utilitarian standpoint, and it might be profitably discussed by the Society of Medical Officers of Health.

CEREBELLAR AND SPINAL SYMPTOMS IN MEMBERS OF THE SAME FAMILY.

IN a recent number of the *Revue de Médecine* Dr. Pauly and Dr. Bonne record an interesting observation of three brothers who showed similar symptoms of disturbance of the nervous system. There was no evidence of hereditary weakness, for several sisters were quite healthy and there was no morbid condition evident in the parents. The symptoms commenced in the two older brothers between the ages of twelve and fourteen and in the youngest brother at the age of six years. Difficulty in walking was the first thing noticed in the two elder brothers, nystagmus in the youngest. In all these during rest the legs were slightly flexed and could not be fully extended. There was also marked contraction of the adductors. The gait showed a combination of weakness and spasticity. In the youngest patient, who was eleven years of age at the time of the observation, walking was no longer possible except with assistance. There was no ataxy either in standing or in walking. There was no paralysis in the arms, but there was a little tremor on voluntary movement. In all these brothers there were nystagmus, slow and monotonous articulation, exaggerated reflexes, and commencing optic atrophy. Sensation and intelligence were quite undisturbed. The cases resemble closely those described a few years ago by Dr. Sanger Brown and by Dr. Pelizäus and Dr. Higier and probably depend upon defective development of the nervous system analogous to what is found in Friedreich's ataxy, although not identical with the conditions underlying that disease.

OPENING OF A NEW HOME AT THE CHALFONT EPILEPTIC COLONY.

THE experiment made by the National Society for the Employment of Epileptics of establishing an industrial colony where sane epileptics who were debarred by their affliction from obtaining employment might not only find opportunities for useful work but might also receive the care and supervision necessitated by their complaint has proved so successful that the number of colonists will shortly exceed 100. On May 12th a large number of supporters of the institution visited the colony, which is situated in a very beautiful part of Buckinghamshire. Among those present were the Duke and Duchess of Marlborough, the Duchess of Bedford, Sir

William Broadbent, Mr. and Mrs. Passmore Edwards, Mr. Micholls (chairman of the committee), Dr. Buzzard, Colonel Montefiore, Dr. Fletcher Beach, Dr. Nicolson, C.B., Miss Caine, M.B. Lond., Mrs. Burgwin, and Dr. Colman. The new Victoria Home for men was opened by the Duchess of Marlborough and afterwards the foundation stones of two new homes, one for boys and one for girls, were laid by the Duke of Marlborough and Mrs. Passmore Edwards respectively. In responding to a vote of thanks the Duke of Marlborough expressed his firm conviction that the important questions for public men in the future would be those dealing with the best means of ameliorating the condition of the masses of the population. He considered that although the initiation of charitable enterprises was in this country left to private generosity and enterprise, yet they ought to receive some encouragement at the hands of Government. There are now four homes open, each accommodating 20 colonists, and when the children's homes are open there will be 40 more inhabitants of this little village. The chairman announced that the committee were anxious to obtain funds in order to build a house for a resident medical officer. With so large a number of colonists there should certainly be no delay about such a step. When children are admitted the need for a medical superintendent will be even more urgent than it is at present and we have good reason to believe that no application for a Government grant towards the expenses of education is likely to be entertained until there is a resident medical officer. Up to the present nearly all the homes have been built through the munificence of one man—Mr. Passmore Edwards. Surely there are other wealthy men, knowing possibly from their own family experience how great a boon such an institution must be to the poor, who can come forward and make it possible for the committee to provide adequate medical supervision and prompt medical assistance in cases of accident or emergency.

STREET NOISES.

AT last a step in the right direction has been taken with regard to the curse of street noises. It will be remembered that in November, 1897, a man named Kruse was convicted by the Kentish magistrates and fined £1 for conducting a religious service in the open air after being requested to desist. The conviction was obtained under a by-law of the Kent County Council to the following effect:—

"No person shall sound or play upon any musical or noisy instrument or sing in any public place or highway within fifty yards of any dwelling house after being required by any constable or by an inmate of such house personally, or by his or her servants, to desist."

The conviction was appealed from and judgment was at length delivered on May 14th in the Queen's Bench Division, the court consisting of the Lord Chief Justice, Sir F. Jeune, Lord Justice Chitty, and Justices Mathew, Wright, Darling, and Channell. The Lord Chief Justice delivered a judgment which was concurred in by all except Mr. Justice Mathew, and Sir F. Jeune gave a judgment to the same effect. The conviction was upheld. Lord Russell remarked that the contention that the by-law should contain the qualification that the music should be an annoyance would render it inoperative, for who was to be the judge of what was or was not an annoyance? Now if the Kent County Council can pass a by-law of this kind there is no earthly reason why the London County Council should not do likewise. Only in addition to the "music" question it must contain a clause to prohibit the yelling of newspaper hawkers. As we have said over and over again there are plenty of newspaper sellers who do not yell and who yet make a living. The nuisance daily gets worse, the Strand and Piccadilly-circus are simply unbearable for most of the day, while the more strictly residential districts are pestered on Sundays with small boys crying the ordinary Sunday papers and in addition since the war began with "sturdy vagrants" who howl "late Sunday speshuls" containing, to judge by the following morning papers, lies of the most unblushing description. The honest, if not sweet-voiced, costermonger may be put up with, but the "runner" or purveyor of what used to be called "cocks"—i.e., the "awful slaughter" innuendoes—must be put down with a heavy hand and the sooner the London County Council see to it the better.

THE ROYAL COMMISSION ON THE DISPOSAL AND TREATMENT OF SEWAGE.

IN our remarks on the constitution of this Commission in an annotation in THE LANCET of May 14th we should have stated that two of the commissioners are engineering authorities—viz., Major-General C. Phipps Carey, R.E., one of the deputy engineering inspectors to the Local Government Board, and Mr. C. P. Cotton, M.I.C.E., chief engineering inspector to the Local Government Board for Ireland. It is probable that sub-commissioners will also be added who are competent to investigate the bacteriological and chemical sides of the question.

ENGLISH MEDICAL MEN IN ITALY.

THE General Medical Council and the Royal Colleges of Physicians of London and Surgeons of England are to be congratulated on the result of their efforts to induce the Italian Government to abandon its intention of making it illegal for English medical men to practise in Italy without acquiring an Italian diploma. Such a proposal in all the circumstances and relations of the two countries was felt here to be unreasonable and illiberal and unworthy of the Italian Government and people. Its abandonment, on the other hand, will be regarded as another proof of the friendly and generous feeling which Italy has always shown to our country and countrymen. The profession will not forget the service which Lord Salisbury and the English Ambassador at Rome have rendered in regard to this matter.

HEMANS v. COLGATE AND ANOTHER.

AN action against two medical men has been successfully defended by the London and Counties Medical Protection Society through their solicitors, Messrs. Le Brasseur and Oakley. The action was brought in the Queen's Bench Division, before the Lord Chief Justice and a Special Jury, by Mr. Henry Hemans, an engineer in England and Buenos Ayres, against Dr. Henry Colgate of Eastbourne, who acted as the plaintiff's medical adviser, and Mr. George Arthur Skinner, surgeon, of the Waterside Hydropathic Establishment, Upperton-road, Eastbourne, in whose institution the plaintiff was received and detained, it was alleged, from Nov. 29th, 1895, till Jan. 9th, 1896, when he escaped. He sought to recover damages for negligence in treatment and for false imprisonment. The plaintiff's case was one of overwork and required, according to Dr. Colgate, the Weir Mitchell treatment and rest for six weeks. He wished to go to Matlock, but went to the Eastbourne establishment on Dr. Colgate's advice. He soon complained of noises and that the establishment was unsuitable for him. He was dissatisfied with his room and with the environment generally. He alleged that his clothes were taken away and that a letter to his daughter to remove him was suppressed. Under cross-examination these statements were much weakened. The door was open all day and he admitted that it never occurred to him that his clothes were in the wardrobe. At the close of his evidence the jury intimated that in their opinion no case had been made out. The Lord Chief Justice seemed to be of the

same opinion throughout and he observed that in the plaintiff's state of health he might have regarded as troubles things which would not have affected other people. Finally verdict and judgment were entered for the defendants with costs. We need not say that we concur in the justice of the verdict and congratulate the defendants on such a righteous end to the annoyance which such a case implies to medical men.

"THE REMUNERATION (P) OF POOR-LAW MEDICAL SERVICE."

MR. HORACE SWORDER, the medical officer of health of Luton Borough, writes to us to point out the inaccuracies in a paragraph which appeared recently in the *Daily Telegraph* and upon which we founded some comments last week. Mr. Sworder is not medical officer to the Union Workhouse and has not to supply 10,000 or any other number of bottles of medicine out of his salary which, moreover, was not correctly stated. We are sorry to have misrepresented Mr. Sworder's position.

MEDICAL SOCIETY OF LONDON: ANNUAL CONVERSAZIONE.

THE 1897-98 session of the Medical Society of London was closed on May 16th by the delivery of the annual oration and a conversazione of the Fellows and their friends. The orator for the year was Dr. Frederick Roberts and his oration, which appears in full in another part of this issue, was listened to by an overflowing audience. Sir William Broadbent proposed and Mr. A. E. Barker seconded a vote of thanks to Dr. Roberts for his eloquent and interesting address and the vote was enthusiastically carried. A conversazione followed in the society's rooms which were beautifully decorated with palms. The annual gathering was certainly one of the most successful which has taken place, thanks to the arrangements of the honorary secretaries, Dr. Robert Maguire and Mr. W. H. Battle, and the registrar, Mr. Hall.

LONDON'S PLAYING FIELDS: AN APPEAL.

AMONG the many things which are needful for promoting the health of London's teeming millions is the provision of adequate space in which the workers can indulge in open-air games for recreation; but owing to the encroachment of the builder the provision of such spaces becomes year by year more difficult. The London Playing Fields Committee, of which H.R.H. the Duke of York is President, have already provided over 100 cricket pitches and 18 football grounds in various places round London for the use of clerks, workingmen, and boys who are able to pay a small sum for maintenance, thus leaving the limited area in public parks and commons entirely free for the use of the poorest players. The committee, however, hold these grounds on lease only and from time to time they have to be given up for building purposes. One of the spaces held by this committee is at Raynes Park, Surrey, called the Prince George's Ground, after the name of the Royal President of the committee. This comprises about 25 acres and the field has been laid out at a cost of £1100 for football and cricket. It is held under a lease of 10 years dating from 1891, but up to the end of the present year the committee have the opportunity of purchasing the site for the sum of £10,000. Towards this amount H.R.H. the Duke of York headed a subscription list last year with £10 and H.R.H. the Duchess of York gave £5. The appeal has resulted in a sum of £1345 paid or promised, but as it is necessary to complete the purchase fund in 1898 the committee ask the help, not only of lovers of cricket and football, but of all who realise the importance and the difficulty of maintaining the bodily health and development of our vast city population. Donations to the fund will be received by the chairman of the London Playing Fields Committee, the Hon. E. Chandos Leigh, 45, Upper Grosvenor-street, W.; Mr. E. N. Buxton, Knighton, Buckhurst-hill, Essex (treasurer); Mr. T. Hall Hall, 5, New-square, Lincoln's-inn, W.C. (deputy-chairman); Mr. H. D. G. Leveson Gower, 11, Birchin-lane, E.C. (secretary); or they may be paid directly to the bankers, Messrs. Barclay and Co., Limited, 1, Pall-mall East, S.W. All cheques and postal orders should be made payable to "Prince George's Ground Purchase Fund" and crossed "Barclay and Co., Limited."

PERIODICAL PARALYSIS OF THE SUPERIOR OBLIQUE MUSCLE.

IN a recent number of the *Neurologisches Centralblatt* an abstract appears of an interesting case recorded by Dr. Aug. di Luzenberger in *Manicomio* XIII. The patient was a man, aged twenty-nine years, whose mother had suffered from migraine. At the age of twelve years, after a long walk in the sun with his head uncovered, he was seized with severe unilateral headache, with loss of appetite, nausea, and diplopia. At first the attacks occurred almost every week, lasting a day, and the headache and diplopia came and went almost simultaneously. In the course of a year they became less frequent, but lasted longer, finally persisting for fifteen days. The last attack observed by Dr. Luzenberger lasted twenty days. In this the headache and nausea began in the afternoons and lasted till bed-time. The diplopia, however, was continuous. The attack was accompanied by loud pulsation in the head and the right temporal vein was better filled than the left, although there was no asymmetry of the head. The diplopia was found to depend upon paralysis of the superior oblique muscle and the eyes presented no other abnormality. The headache was got rid of by moderate doses of bromide, but the diplopia persisted for fifteen days' longer and then disappeared without leaving any change in the eyes. The temporal vein also on the side on which it had been distended became normal. Dr. Luzenberger suggests that the underlying cause of the phenomena is a periodical swelling of the cavernous sinus with consequent pressure on the first branch of the fifth nerve and also on the fourth. The case, of course, is similar to others which have been described in which, however, the paralytic phenomena have been the result of an affection of the third nerve.

A COMMITTEE OF INQUIRY INTO THE ALLEGED INJURIOUS EFFECTS OF X RAYS.

IT having been alleged that injurious effects on the human body have been caused by exposure to x rays it was decided at a meeting of the council of the Roentgen Society on April 5th to nominate a committee to collect information on the subject. The following members were selected, with power to add to their number: Professor Sylvanus P. Thompson (president of the society), Dr. David Walsh (secretary of the society), Mr. Thomas Moore, Dr. Barry Blacker, and Mr. Ernest Payne (Hatchlands, Cuckfield, Sussex), who is acting as secretary to the committee. We are informed that the committee will be glad to hear from all workers with x rays of any case of injury that may have come under their notice after exposure of a patient to the rays and in order to obtain accurate reports the committee have prepared a set of questions which have been framed with a view to elicit opinion and collect information to show whether the injury was the result of any of the following causes: (1) the x rays themselves directly; (2) some electrolytic or electro-thermal action of a leakage discharge

current from the leads or from the terminals of the tube; (3) some action due to the varying electrostatic charges on the surface of the tube; (4) some combination of these; (5) some other hitherto unrecognised kind of radiation emitted simultaneously with the x rays; or (6) some other cause hitherto unobserved. The secretary of the committee will be glad to send copies of the questions to any medical man or other worker in x rays who may know a case about the circumstances of which he is willing to give particulars. No names will be published in connexion with the information supplied except by the distinct consent or request of those concerned.

UNIVERSITY OF LONDON.

THE election of a Fellow of the Senate of the University of London will take place on Tuesday, May 24th, and the nomination lists as well as the addresses are in the hands of the graduates. The nomination is largely in favour of Mr. Fletcher Moulton, Q.C., who will evidently poll a very considerable majority of country graduates, whilst almost every graduate who is a London teacher is supporting Dr. Benson. The question, therefore, resolves itself into this: shall country graduates determine the needs of a local University for London, and shall uniformity of the examination standard take the place of a well-considered curriculum of education? The suggestion of Mr. Moulton's committee that "teaching functions should be added to the present work of the University through a supplemental charter framed so as to confer the necessary powers" is obviously impossible and would be opposed by every teaching institution in London.

A CONVERSAZIONE will be given by the British Balneological and Climatological Society on Wednesday, June 8th, at 9 P.M., at Limmer's Hotel, Conduit-street, when Dr. G. Vivian Poore will deliver an address on "Circumstances which Influence the Effectiveness of Climatic Treatment." There will be an exhibition of meteorological instruments by Messrs. Negretti and Zambra and Dr. W. S. Hedley will show a Radiant Heat Apparatus.

THE dinner given by the Lord Mayor of London in the interests of the London Hospital on Wednesday night last proved a very successful function. New annual subscriptions to the extent of £4500 were announced and donations amounting to £39,000. Among these donations were two anonymous ones, of £25,000 and £10,000 respectively.

WE understand that Mr. Collings has drawn up a draft report which will be presented to the Petroleum Committee on June 10th. The end, therefore, of a very long and protracted inquiry is near and the report will be awaited with interest by a large number of persons.

SIR MATTHEW WHITE RIDLEY, in answer to Mr. Pickersgill and Sir Charles Dilke, has intimated in the House of Commons his intention to order a prosecution in respect of an alleged breach of the Factory Acts in connexion with recent cases of phosphorus poisoning.

HER MAJESTY THE QUEEN has sent £100 to the London Hospital in aid of the special appeal now being made.

MEDICO-PSYCHOLOGICAL ASSOCIATION. — The spring meeting of the Northern and Midland Division of this association will be held at Cheadle Asylum, near Manchester, on May 25th, 1898. Mr. G. W. Mould will open a discussion on the new Lunacy Bill, and will also provide lunch and dinner for the members attending.

THE REGISTRAR-GENERAL'S ANNUAL SUMMARY FOR 1897.

THE Registrar-General's annual summary of births, deaths, and causes of death for the year 1897 has just been issued. Like its predecessor for 1896 this summary contains a useful and succinct account of the mortality, not of London only, but of thirty-two of the other great English towns, and if only arrangements could be made for its production somewhat more promptly than at present after the close of the year to which it relates the value of this publication both to the sanitary branch of our profession and to the public generally would be greatly enhanced. In its present advanced state of development, which it attained for the first time in 1896, the summary seems to leave little to be desired taken as a record of mortality alone in our great centres of British industry. But we confess to a feeling of disappointment at the thought that although so much has been done of late years to perfect the English system of notification of those important and destructive maladies which are communicable from person to person no attempt has hitherto been made to collect and publish a record of such maladies, although they are known to levy an oppressive death-rate on the most valuable lives of our population. The summary now before us shows that in the Statistical Office of Somerset House the State possesses a department competent to deal with the national records of mortality in such fashion as to extract from them the maximum of instruction for preventive purposes which such partial records are capable of rendering. It would therefore seem to need but a slight addition to the work of that office if a similarly detailed record could be added of those cases of infectious sickness which are not necessarily fatal, but an accurate knowledge of the prevalence of which in our industrial centres is, from a sanitary standpoint, even more valuable than the most accurate statement of mortality could possibly be. The returns of the Registrar-General are at present published at weekly and quarterly as well as yearly intervals, and it is reasonable to surmise that as a properly trained staff at Somerset House is constantly engaged in this work the development now suggested would necessitate but slight modifications in the establishment already existing. The deaths registered within the 52 weeks of the year 1897 in the 33 great towns of England were equal to a rate of 19·1 per 1000 of the aggregate population, or 1·7 per 1000 more than the death-rate of England and Wales in the same year. Calculated with due regard to the differing age-constitution of the several populations, the death-rates ranged from the lowest, 13·6 in Croydon and 15·2 in Brighton to the highest 26·8 both in Liverpool and in Preston. The corrected death-rate of London in 1897 was 19·4 and was considerably lower than the average rate in the preceding ten years. The presence of large public institutions in certain parts of London unduly raises the recorded death-rates of the areas in which they are situated, whilst the mortality of other areas from which patients have migrated to those institutions is unfairly lowered. Until the deaths occurring in public institutions have been distributed to the sanitary areas from which the patients originally came it is impossible to calculate reliable rates of mortality for these areas. The rates of mortality for metropolitan sanitary areas were published for the first time in the annual summary for 1896, the establishment of a quinquennial census for London having rendered it possible to frame trustworthy estimates of district populations.

Some of the London sanitary areas afford striking examples of the necessity for the distribution of mortality just referred to. The City of London, for instance, contains amongst other institutions St. Bartholomew's Hospital and the City workhouse. The deaths registered last year in the City numbered 1054, but of these 653 occurred in public institutions and were mostly deaths of persons belonging to outside areas. After distribution of these deaths the number belonging to the City was only 642. The uncorrected death-rate of London City therefore stood at 35·0 per 1000, whilst the corrected rate did not exceed 21·3. On the other hand, in the Bermondsey sanitary area only 1411 deaths were registered last year, but when the deaths of Bermondsey residents which took place in institutions outside its

boundaries are included the death total is raised from 1411 to 1883 and the death-rate from 16 5 per 1000 to 22·1. In the same manner the death-rate of St. George-in-the-East was raised from 21·9 to 26·4 and that of St. Saviour's from 17·1 to 24 6. Infantile mortality—i.e., the proportion of deaths under one year to births registered—was equal last year to 177 per 1000 in the 33 great towns and was 1 per cent. above the decennial average. The proportions ranged from the lowest, 131 in Huddersfield and 144 in Brighton, to 219 in Salford, 220 in Burnley, and 262 in Preston. In London infantile mortality averaged 159 per 1000 births and was slightly above the average. After distribution of the institution deaths infantile mortality was equal to 116 per 1000 in Plumstead, 121 in Stoke Newington, and 130 in the City of London; in the other metropolitan areas it ranged upwards to 193 in Limehouse, 195 in St. Saviour's, and 197 in St. George-in-the-East. A table is given which shows in a summary form the number of lives saved and the number lost in London last year as compared with the previous decade. The net gain in life saved is represented by 7651 lives. In other words, had the average death-rate in 1887–96 continued throughout 1897 there would have been sacrificed 7651 lives in addition to those actually lost by death. As compared with the average there was an excess last year of 222 deaths from diphtheria, 1156 from diarrhœal disease, 475 from cancer, 282 from premature birth, 135 from urinary disease, and 134 from accident. Under most of the other headings the registered mortality was below the average. There were only 18 deaths from small-pox last year in the 33 great towns, as compared with 732, 450, 120 and 25 respectively in the four preceding years. Of these deaths 16 occurred in London, 1 in Bristol, and 1 in Hull. Measles caused a mortality equal to 0 55 per 1000 in the great towns. The rates varied from 0 03 in Norwich and 0·07 in Leicester to 2 22 in Salford and 2·77 in Preston. In London the mortality from this disease was at the rate of 0·43 per 1000 and was therefore above the average. In metropolitan sanitary areas the rate ranged from 0·02 in Paddington to 1·42 in St. George-in-the-East. Scarlet fever caused a mortality of 0·18 per 1000 in the great towns, against an average of 0 27. In Preston and Bradford the rate was only 0 04 per 1000, but it rose to 0·32 in Huddersfield, 0·33 in Liverpool, and 0 35 in Leicester. Scarlet fever caused a mortality of 0·18 per 1000 in London, which was decidedly below the average; the rate did not exceed 0·06 per 1000 in Marylebone and Stoke Newington, whilst it equalled 0·40 in Bermondsey and 0·54 in Rotherhithe. The mortality ascribed to diphtheria averaged 0·31 per 1000 in the great English towns, which is below the rate in either of the four previous years. In Sunderland and Preston the rate was only 0 03 per 1000, but it was as high as 0·57 in Burnley and 0 62 in Wolverhampton. In London the rate averaged 0 51 per 1000 and was lower than in either of the three preceding years. In metropolitan sanitary areas the diphtheria rate ranged from 0·13 in St. James's, Westminster, and 0·17 in St. Olave to 0 73 in Clerkenwell and Bermondsey and 0 80 in Woolwich. Whooping-cough gave rise to a death-rate of 0·41 per 1000 or 0·14 below the average in the 33 great towns. The lowest rate was 0·07 per 1000 in Croydon and in Swansea and the highest 0·31 in Salford and in Sheffield. In London the death-rate from this disease averaged 0·41 per 1000 and ranged from 0·11 in Kensington and 0·13 in Lee to 0·73 in Bermondsey and 0·74 in Clerkenwell. Continued fevers, mainly enteric, gave rise to a mortality of 0·18 per 1000, which is slightly below the average. The lowest rates were 0·07 in Croydon and in Swansea, and the highest 0·31 in Salford and in Sheffield. The rate averaged 0·13 in London and was slightly below the decennial average. Among sanitary areas, the lowest rates from enteric fever were 0·05 in Rotherhithe and Plumstead, and the highest 0 29 in Stoke Newington and 0·30 in the City of London. In the 33 great towns diarrhœal diseases caused an average mortality of 1·24 per 1000, which was higher than that of either of the 10 preceding years. The lowest rate was 0·21 in Swansea and the highest 2·23 in Preston and in Hull. The rate averaged 0·92 in London and ranged from 0·16 in St. Martin-in-the-Fields to 1·55 in Shoreditch and 1·81 in St. George's, Southwark. The death-rate from phthisis in Registration London was equal to 1·71 per 1000, as compared with rates of 1·83 and 1·73 respectively in the two years preceding. After distribution of the deaths from phthisis which had occurred in public institutions the death-rate from that disease in the metropolitan areas ranged from 0·74 in Hampstead, 0·94 in Lewisham, and 1·10 in Lee to 3·11 in St. Luke, 3·22 in St. Saviour's, and 3·36 in the Strand sanitary area. Unfortunately the Registrar-General's summary does not afford the means of comparing the death-rates from phthisis in extra-metropolitan districts; this is one of the very few defects which we have noticed and would gladly see remedied in future numbers of what we regard as a most valuable publication.

REPORT OF THE ROYAL COMMISSION ON TUBERCULOSIS.

III.—MINUTES OF EVIDENCE AND APPENDICES.[1]

THE Blue-book was published at the end of last week, and much useful information will be found in the Appendices it contains. The first place is given to the "Report on a Visit paid to certain Places in Belgium, Germany, and Denmark," which is signed by three of the Commissioners and Professor J. McFadyean, who accompanied them in place of Sir George Brown, who was unable to leave London at the time. This Report is dated June 12th, 1897, and it is almost a pity that it could not have been published separately. On many points it amplifies the general Report, in connexion with which it should be read.

The Belgian Government, in 1895, was the first to draw up comprehensive regulations for dealing with bovine tuberculosis, and it is interesting to note that they were led to do so from the knowledge gained as to the prevalence of the disease by the complete system of meat inspection instituted in 1890. The regulations provided for the very extensive use of tuberculin by veterinary surgeons, and animals reacting to the test were to be isolated from the healthy and their sale was only to be allowed for the meat market, the limit of time for slaughter being one year. Animals showing clinical symptoms of the disease were to be slaughtered at once. Compensation was given under certain restrictions to the owners of cattle the carcasses of which were condemned as unfit for food. Provision was also made by the erection of large quarantine sheds at each place where a line of railway crossed the frontier for testing with tuberculin animals imported from neighbouring countries.

At the time of the Commissioners' visit the regulation had been in force about a year and during that time some 22,000 animals had been tested, involving an expenditure of about £40,000 in compensation.

Many persons have urged the adoption in Great Britain of a similar method for dealing with bovine tuberculosis, but the impression received by the Commissioners in Belgium was that the attempt to stamp out the disease in the native dairy stock had proved too onerous to be sustained and that if the internal measures prove unworkable or a failure the effect of the frontier quarantine, so far as it was applicable to tuberculosis, must be regarded as superfluous and extravagant.

This first measure, admittedly experimental, was found to be too drastic, as the tuberculin test was made almost compulsory on all cattle in consequence of the fact that if tuberculosis was found in an animal post mortem none of the other animals which had occupied the same shed were allowed to be sold except for the meat market unless they failed to react to the test. Since the visit of the Commissioners the law which they saw at work has been modified in such a way that in future action will only be taken by the State in cases where animals are visibly affected with the disease. The terms of this new measure are printed in full in the Appendix.

In the same Report, under the heading "Germany," a concise account is given of the system of meat inspection in the public slaughter-houses, together with valuable statistical matter on the subject taken from the annual reports by the directors of the abattoirs in Leipsic and Dresden. A description is also given of the method of insurance against loss by condemnation of carcasses adopted by the farmers and butchers in these two cities.

The Commissioners state that "in Copenhagen we found ourselves with men who were able to show a very remarkable

[1] Nos. I. and II. were published in THE LANCET of April 30th and May 7th, 1898, respectively.

degree of success in grappling with tuberculosis and in eliminating it from their herds," but as they quote in their general Report the description of their visit to Denmark it is unnecessary to refer further to it here.

The Appendix contains important statistics, such as have never appeared elsewhere, on the mortality from various forms of tuberculous disease in several age periods from 1851 to 1895, furnished by Dr. Tatham, Superintendent of Statistics, General Register Office. The information was called for from a desire on the part of Commissioners to learn whether it was possible from mortality figures to establish a relationship between the consumption of meat and milk and tuberculous disease in man. The tables comprise (*a*) all forms of tuberculous disease, (*b*) phthisis, (*c*) tabes mesenterica, (*d*) tuberculous meningitis, and (*e*) scrofula and other forms of tuberculous disease. Dr. Tatham has supplied a memorandum in explanation of the tables, his conclusion being that in the course of the last forty-five years there has been a substantial diminution in the mortality attributed to tuberculous disease in England and Wales, but that the data at our disposal do not warrant the attempt to estimate either the amount or the proportion of decrease which has taken place between the earlier and the later periods referred to. Two diagrams which he appends—one showing the annual variations in the mortality from tabes mesenterica and tuberculous meningitis from 1875 to 1895, the other showing the same with regard to tabes mesenterica and diarrhœa—bring out the close connexion which exists between the latter two diseases, as the curves in both rise and fall together. This relationship between diarrhœa and tabes mesenterica he adduces in support of his view that the latter is a very indefinite cause of death, and that the former is not unfrequently mistaken for it.

Somewhat similar tables are also furnished of the death-rate from tuberculous diseases in Glasgow by Dr. Chalmers and in Manchester by Dr. Niven.

A useful summary appears of the enactments in general statutes and of the general orders and model by-laws of the Local Government Board which are applicable to London and England and Wales, relating to (1) unsound meat, milk and milk products, (2) slaughter-houses, and (3) dairies, cowsheds and milkshops. For purposes of comparison there is a similar summary of the Scottish general and local Acts on meat and milk inspection, and of the regulations in force in the principal British colonies and in the United States. Seeing that much has been done in Continental countries to advance our knowledge of the subject, translations of the regulations on meat and milk inspection, with especial reference to tuberculosis in Germany, France, Belgium, Denmark, Norway, and Switzerland, have been made by the secretary. The Blue-book therefore forms a useful reference work on these points.

THE IRISH LOCAL GOVERNMENT BILL.

II.[1]

In a previous article a sketch was given of the provisions and general tendency of the Bill at present before Parliament for the reform of local administration in Ireland. Attention was directed to its broadly democratic character, its general similarity, with such modifications as the special circumstances and needs of the sister island demanded, to the Bills adopted in recent years in England and Scotland, the generous character of its financial arrangements, and some of the points which specially affect the interests of the medical profession. The Bill has at all events the merits of courage, thoroughness, and consistency. It does not attempt to mend or tinker. It makes no pretence of patching up a system which is recognised to be an anachronism and which, whatever its merits, can manifestly be no longer maintained. It sweeps away most of the cherished and time-honoured privileges of the Irish gentry and leaves them, if they wish to retain a share in local administration, to take their chance at the polls. The grand jury system, as is now recognised by everyone whose opinion is worth considering, belongs to an order of things which has passed away for ever. As Judge O'Connor Morris says: "The grand jury system was part and parcel of the Protestant Ascendancy which until recent times was the distinctive feature of all Irish government. The grand juries were long confined to the Protestant caste; they were nominated, not elected, bodies composed of the leading landed gentry; they had almost absolute control over the administration of their respective counties and had a power to raise a local rate to defray the charge, a mode of taxation imposed on the occupiers of the soil in four-fifths of Ireland, at least the peasantry of the subject Catholic people. ..... The Irish Protestant squirearchy knew how to rule and every grand jury had good men of business; the police they appointed kept Whiteboyism down; the roads they constructed were the admiration of Arthur Young." By degrees the powers of the grand juries were curtailed and the central government of Dublin Castle assumed some of their functions. "The grand juries are still assemblies of county magnates; though they have been thrown open to Catholics since 1793, they are still for the most part composed of Protestants. They are selected by the sheriffs of their counties—that is, virtually, by officials of the central government; they are subject to no kind of popular choice. In theory and to a great extent in fact they administer the local affairs of the counties, including those of the smaller towns and villages of these; they make presentments—i.e., vote money for the chief public buildings, the main roads, and other public works within the counties and generally their towns; they impose a rate known as the county cess to defray the charges of these and other expenses. They are, however, ruled at many points by the central government; this appoints several of their chief officers; it subjects their expenditure to a strict audit; it has long replaced their local police by the great constabulary force of the State, and for many years they have been obliged by law to make 'imperative presentments' for public works of different kinds, such as hospitals, lunatic asylums, and courthouses, and to repay advances made to them by the Treasury." In recent times they have acquired additional powers—viz., to assess compensation for malicious injuries which is levied upon the ratepayers, and to provide for extra police in districts where crime exceeds a certain rate. The "presentments" of the grand juries require to be fiated by a judge of assize.

The Bill affects materially Irish Poor-law administration. The Irish Poor-law dates from 1838. Ireland is divided into 159 unions, and these are subdivided into electoral divisions and wards for the administration of the law. The unions are placed under boards of guardians which are controlled by the Poor-law Commissioners and to some extent by the Local Government Board. Every electoral division in rural districts returns a guardian elected by the ratepayers by a cumulative vote. The elected guardians form only one-half of the board, the other half consisting of *ex-officio* guardians. In addition to administering the Poor-law the guardians are the sanitary authorities for all rural and many urban areas. The charges of the unions are defrayed by a poor-rate assessed by the boards of guardians. In the case of lands and tenements of more than £4 in value the poor-rate is paid by the occupier like the county cess, but the occupier if he is rated at £4 or upwards deducts half of the poor-rate, which is paid by the landlord. If the occupier be rated at £4 or less the landlord pays the whole of the poor-rate. It will thus be seen that the Poor-law administration is the most democratic part of Irish local government, but the *ex-officio* guardians have been a stumbling-block and the present Bill proposes to sweep them away altogether. The boards of guardians have done their work fairly well and if fault must be found in some instances, it should be recognised that their task has often been a difficult one. They have had to deal with a great mass of poverty and to endeavour at the same time to keep down the rates. No doubt many of the poor houses are overcrowded, in many cases they are quite undermanned as regards medical attendance, and the retention of lunatic cases which should have been transferred to the asylums has sometimes amounted to a scandal. The boards of guardians have not always treated their medical officers well or seconded their efforts to bring the work of the Poor-law infirmaries and hospitals in line with modern medical and surgical progress. They have been often grudging in their allowances as regards extra fees of any kind and also with regard to leave of absence. Perhaps these things might, under all the circumstances of the case, have been expected. It is to be hoped that the new district councils, which will

[1] No. I. was published in THE LANCET of May 14th, 1898.

henceforth discharge the functions of boards of guardians, will do better.

The Bill takes from the grand juries all their fiscal and administrative functions, which will be transferred to the county councils, but leaves them the same criminal jurisdiction which grand juries in England possess. The county councils will obtain certain powers never possessed by the grand juries—viz., the assessment and levying of the poor-rate, the control of the lunatic poor, and certain powers enabling them to cope with cases of exceptional distress. The subordinate bodies, or district councils, will be elected on the same lines as the county councils, and there will be one such council for each union. These district councils will vote the lesser public works and they will take over the duties and privileges of the boards of guardians, excepting the assessment of the poor-rate, which, as already stated, will rest with the county council. All the assemblies created by the Bill will be subjected to the jurisdiction of the superior courts of Ireland, and the Local Government Board, though stripped of most of the large powers which it at present exercises, will retain a certain amount of control over the councils for the counties and other districts as regards expenditure on roads and it will have a voice in the appointment of some of their chief officers.

It will be noticed that there are many things which the Bill does *not* do. It does not seem to touch private bill legislation, which apparently will go on as before in London. This is a palpable blot which will some day demand remedy. It is not reasonable that no Irish railway can be constructed, no dock built, no extension of a municipal boundary effected, no new water-supply introduced, no sanitary reforms instituted without a Parliamentary inquiry at Westminster—an inquiry often tedious and always costly. It is not to be denied that there is some counterbalancing advantage in having vexed Irish questions tried by bodies so competent and so impartial as an average Parliamentary Committee, but on the other hand this machinery is quite too cumbrous and elaborate for many of the questions which come before it. Ireland stands as regards this question on a somewhat different footing from England and Scotland. She is a poor country and can often ill afford the cost of a Parliamentary inquiry. Then the cost of bringing witnesses to London is considerable and greater than that incurred under similar circumstances for an English or Scotch bill. It is to be hoped that in the future some machinery may be devised for dealing on the spot with some of the questions above mentioned. The Bill does not seem to contemplate any collective action of two or more counties for any purpose whatever. It is generally believed that a very important member of the present Government was at one time in favour of provincial councils in Ireland, i.e., a council for each of the four provinces of Leinster, Munster, Ulster, and Connaught. This plan whatever might have been the objections to it from other points of view, would at least have secured united action on the part of much larger areas than that of the existing counties. It must be remembered that England and Scotland present no analogy to the Irish provinces. Leinster, Munster, Ulster, and Connaught are each definite entities, with a good deal of local feeling and local tradition. Whether any plan could be devised for enabling several counties to act together for a common object—an end certainly in itself desirable—is worth the attention of practical politicians. Apparently the Bill does not contemplate anything of the kind. It is important to note that the Bill leaves the control of the police in the hands of the central government, a provision the wisdom of which will be challenged only by extreme partisans.

The debate on the second reading of the Bill showed clearly that there is no hearty or thoroughgoing opposition to the measure on the part of any important section of the House of Commons. The party led by Mr. Dillon and a section of the English and Scotch Radicals object to the financial regulations as involving a dole to the Irish landlords, but the general feeling of the House clearly was that without some provision of this sort the Bill would be quite an impossibility. Some Irish Unionists, on the other hand, view with alarm the large taxing powers with which the new councils—to be elected on a low franchise and frankly democratic in constitution—will be entrusted. They would desire some security to prevent owners of property from over-taxation and extravagance on the part of the councils. As was pointed out in explaining the financial provisions of the measure, it has been the aim of the framers to discourage wasteful expenditure and to give the new bodies full benefit of any economy which they may exercise. It is a point worth full and careful consideration whether these precautions are adequate to their declared object, and whether in some way property should not have greater influence upon the new councils. The proposal to elect the members by cumulative vote does not seem a happy one. Some better means could perhaps be found for securing the owners of property against ruinous over-taxation. Mr. Gerald Balfour is of opinion that the new councils will be inclined to parsimony rather than to extravagance. That remains to be seen, but it is not difficult to understand the fears of those who apprehend quite a different state of things.

One of the most important and delicate questions raised by the Bill is the relations henceforth to be maintained between the new councils and the central Local Government Board, and it would appear that some of the points sure to arise are left purposely undetermined. Probably there were good reasons for this course, but it may give rise to serious inconvenience in the future. The Bill is, of course, mainly in the direction of decentralisation, and the Local Government Board will be shorn of many of its most important prerogatives. This was inevitable, inasmuch as the Board is a nominated body and destitute of any true democratic element. The choice lay between enlarging the constitution of the Board or curtailing its powers, and the Government have chosen the latter alternative. Yet it can hardly happen that the relations between the new councils and the Local Government Board will permanently remain as determined by the present Bill. The framers of the Bill have to a certain extent shirked a difficult and perplexing problem, but have probably evaded a present embarrassment at the cost of laying the foundations of future trouble. Is it possible to have a central body in Dublin capable of dealing with some of the questions now decided at Westminster by means of private bill legislation? and if such a body is desirable and practicable, can it be made representative and popular in its constitution? THE LANCET does not concern itself with politics and this particular phase of Irish local government trenches on the political domain. Without expressing any opinion on the subject, it may be pointed out that bold and comprehensive as the present Bill most undoubtedly must be considered, it yet leaves a very important part of the subject untouched.

In his speech during the second reading debate Mr. John Morley dwelt specially upon this point, recalling Mr. Disraeli's remark that the Irish executive was the weakest in the world, and quoting with approval Lord Salisbury's words uttered in 1885: "Local authorities are more exposed to the temptation of the majority to be unjust to the minority when they obtain jurisdiction over a small area than is the case when the local authority derives its sanction from and extends its jurisdiction over a wider area. In a large central authority the wisdom of several parts of the country will correct the folly and mistakes of one. In a local authority that correction is to a much greater extent wanting, and it will be impossible to leave that out of sight in any extension of local authority in Ireland." To set up local bodies with large powers and a popular constitution, and then to attempt to control them by a non-elective Board sitting in Dublin would be a manifestly mistaken and short-sighted policy. The Local Government Board in England has large powers and its authority is seldom if ever challenged, although its constitution is not on a popular basis. But then it must be borne in mind that the President of the English Local Government Board is always a member of the Government of the day, is often in the Cabinet, has a seat in the House of Commons, and is directly responsible to that chamber. The Irish case is different and much more difficult. The present Bill does much but it is clear that it leaves a good deal undone.

The special medical questions which arise in connexion with the present Bill are the following: (1) the selection, position, and duties of dispensary medical officers; (2) the administration of the Poor-law infirmaries and fever hospitals; (3) the administration of the county and municipal asylums for the lunatic poor; (4) the administration of the Public Health Acts in Ireland; and (5) the selection and control of coroners. The remainder of this article will be devoted to some general considerations relating to these various questions, which will be considered in detail in the succeeding article.

Speaking generally, the Bill enlarges the sphere of popular control in medical, as in other, matters. With a few minor

restrictions the new councils will possess complete control of all institutions devoted to the care of the sick and lunatic poor. The powers of the Lord Lieutenant as regards appointments are reduced but not altogether abrogated and some of these powers will be still further curtailed as time goes on. The administration of Poor-law medical relief has been hitherto one of the most democratic parts of Irish local administration, and though it has not been a failure, neither has it been a great or unqualified success. In the election of dispensary medical officers political and sectarian feeling has often had very considerable play, yet it would be untrue to allege that bad appointments have been common or that the electors have disregarded professional fitness in making their choice. The worst that can be said is that the system itself is so imperfect that it would be a miracle if it worked really well. The dispensary medical officers are as a class overworked and underpaid. Their districts are too large and the amount of work is such that it is often quite beyond the powers of any man to discharge it with thoroughness and fidelity while finding time for private practice, which the exiguity of the fixed remuneration makes it indispensable for him to cultivate. It is much to be regretted that for even the worst paid and most laborious appointments there has too often been a shoal of candidates. While such is the case it is almost idle to complain of the disproportion between the salaries and the work. The medical profession has in such matters the remedy in its own hands. If it were once made clear that suitable candidates could not be obtained for these dispensary appointments the elective bodies would soon recognise the necessity of better salaries and a more reasonable adjustment of duties. The Poor-law infirmaries and fever hospitals in Ireland are often overcrowded and the medical service is deficient in quantity though often good in quality. Cases are not unknown where a medical officer is responsible for 500 or 600 patients. It need hardly be pointed out that under such circumstances adequate medical care and supervision are simply physically impossible. The asylums are, on the whole, among the best managed institutions in Ireland and their fortunes under the new *régime* will be a crucial test of the practical value of democratic methods in administration. They are at present controlled by boards nominated by the Lord Lieutenant and usually composed of the local gentry together with some of the leading merchants and professional men. Hence the changes effected under the Bill will be particularly manifest in connexion with asylum administration. Almost the only case in which the Bill tends in a direction not increasingly democratic is in the election of coroners. At present in rural districts they are chosen by popular election on the Parliamentary franchise. Henceforth they will be appointed by the new county councils, just as at present in some of the boroughs they are appointed by the municipal councils. No one will regret this change, the present election of coroners by popular vote being unsatisfactory and, unless under peculiar circumstances, exciting very little popular interest.

THE ASEPSIS OF TOWNS AND DWELLINGS.

AT the request of the Organising Committee of the International Congress of Hygiene and Demography held at Budapest, 1894, Professor Corfield prepared a series of resolutions relating to the sanitary conditions of towns and dwellings. These resolutions were submitted to a special joint meeting of three of the Sections of the Congress and were the subject of a very animated debate. They were ultimately referred to an international committee consisting of the following members: Professor Corfield, London (proposer); Dr. Pistor, Berlin (seconder); Herr Andreas Meijer, chief engineer of Hamburg; M. G. Bechmann, ingénieur en chef des ponts et chaussées, Paris; Professor Fodor, Budapest; Mr. Arthur Cates, architect, London; Herr Berger, chief architect, Vienna; Herr Lindley, engineer, Frankfort-on-Maine; and Dr. A. J. Martin, member of the Consultative Committee of Public Hygiene of France.

The resolutions were revised by the committee and were submitted to the International Congress recently held at Madrid, where they were adopted as resolutions of the Congress. They may be taken to represent the maximum amount of agreement possible at the present moment among sanitarians of different European countries. They are as follows:—

1. That the general health of the population is improved and the spread of diseases prevented in towns and dwellings by the immediate removal of all foul matters and by a copious supply of pure water.
2. That the paving of streets should be smooth and as far as practicable impervious to facilitate cleansing and also to prevent contamination of the subsoil.
3. Special measures should be taken in the construction of houses to prevent the access of ground-air and moisture to the floors and walls.
4. House drains should be arranged so as to avoid stagnation of their contents and to secure a rapid flow to the street sewer. Their walls should be impervious to liquids and gases, they should be freely and continuously ventilated and provided with syphon-traps to prevent the access of foul air to the houses.
5. The public sewers should be so constructed as to ensure the rapid and uninterrupted flow of the sewage to their outlets. They should always be freely ventilated.
6. The streets should be as wide as possible in proportion to the height of the houses; this proportion should be fixed in each locality, regard being had to local circumstances and to climate. Every inhabited building should be well lighted throughout its whole depth and arranged so as to have an access of air from at least two sides.
7. Special regulations should be made in each locality by the public authorities with the view of enforcing the practical application of the principles herein laid down. Governments and municipalities should resolutely and energetically carry out the preceding recommendations, especially those concerning the healthiness of dwellings.

THE "ANYTOLES."

AN important group of oily bodies of interest in medicine has recently been prepared, and the results of an investigation by Dr. F. Loeffler of the University of Greifswald have been embodied in a paper on the subject. The starting-point of the research was ichthyol, from which a definite substance, the active principle, so to speak, was isolated by Helmers some years ago. Ichthyol, as is well known, is a bituminous substance containing a large amount of sulphur and is obtained by treating the products of distillation of a bituminous quartz found in the Tyrol with sulphuric acid and then neutralising with ammonia. It has been used with encouraging results in rheumatic and skin affections and in the early stages of gonorrhœa. Its composition is allied to that of a sulphonate and this has suggested the preparation of sulphonic compounds by the action of sulphuric acid on certain mineral oils, resin oils, and other hydrocarbons. In this way some interesting compounds possessing remarkable properties have been prepared. Perhaps the most important property of these sulphonates of hydrocarbons is that they are capable of rendering certain insoluble substances soluble in water. This capacity varies with the hydrocarbon employed. Eventually it was found that hydrocarbons containing about 10 per cent. sulphur chemically combined are most suitable. If these hydrocarbons are treated with concentrated sulphuric acid, then neutralised with ammonia and the insoluble portion precipitated with alcohol, a product is obtained which possesses a comparatively very great solvent action on bodies insoluble in water. This ammonia salt derived from a hydrocarbon and remarkably rich in sulphur is called by Helmers "anytin" and it is this substance which appears to possess to a remarkable degree the property of rendering substances otherwise insoluble in water soluble, and preparations thus made soluble are called "anytoles." Thus phenol converted into soluble form by means of anytin is called "phenol-anytole." The following anytoles are now prepared, specimens of which have been submitted to us: cresol-anytole, containing 50 per cent. cresols and 50 per cent. anytin; meta-cresol-anytol, containing 40 per cent. meta-cresol and 60 per cent. anytin; creasote-anytole, containing 40 per cent. creasote and 60 per cent. anytin; guaiacol-anytole, containing 40 per cent. guaiacol and 60 per cent. anytin; benzine-anytole, containing 20 per cent. benzine and 80 per cent. anytin; eucalyptol-anytole, containing 25 per cent. eucalyptol and 75 per cent. anytin; peppermint-anytole, containing 25 per cent. peppermint oil and 75 per cent. anytin; wintergreen-anytole, containing 20 per cent. wintergreen oil and 80 per cent. anytin; turpentine-anytole, camphor-anytole, iodine-anytole, &c., all containing similar proportions of active constituent with "anytin."

A series of experiments has been conducted with the view of determining the bactericidal power of such compounds. Obviously some advantage might be gained from the fact of

the active disinfecting agent being made more soluble in water in this combined form. Anytin as a bactericide appears by itself to behave very similarly to ichthyol. Diphtheria bacilli, streptococci and anthrax germs are very susceptible to anytin, whilst other pathogenic organisms are little affected. It appears to be more energetic against diphtheria streptococcus than ichthyol, but less active against other bacteria. Next, the effect of the compounds of anytin with well-known disinfectant substances, that is, the anytoles, was tried with results which showed a remarkable superiority of the anytoles over the disinfectant substances which they contain. Further, meta-cresol-anytole prevents the coagulation of albumin on boiling. A 10 per cent. solution does not appear to damage catgut. After 48 hours the strength of the threads is not affected and they may therefore be exposed for from thirty-six to forty-eight hours by which time all spores will have been destroyed; the threads are then preserved in spirit. As the greater part of the anytole will have been soaked out of the threads by the spirit they may be used without fear of causing irritation. A 3 per cent. solution of meta-cresol-anytole scarcely attacks the skin and a 1 per cent. solution not at all, whilst an ordinary 3 per cent. carbolic solution, which is inferior in action, makes itself felt on many skins. Practical proof of the value of anytole for the disinfection of the hands was obtained. Meta-cresol-anytole appears to be a valuable application for infected wounds. The same anytole appeared to be satisfactory applied as plugs of cotton-wool in the nostrils in ozæna. Solutions of 1 per cent. strength do not irritate the uterine cervical mucous membrane and the mucous surfaces of the vaginal and male urinary tract would appear to tolerate the application of 1 per cent. meta-cresolanytole in the same way. As ichthyol is rapidly fatal to gonococci it might be supposed that meta-cresol-anytole would be even more active. Ichthyol has been internally administered with excellent results in chyluria, and here, again, it is suggested meta-cresol-anytole would probably give even better results. A 3 per cent. solution of meta-cresol-anytole has an energetic action on recent diphtheria processes corresponding to the disinfecting action established on cultures of diphtheria bacilli. It is not, however, able to kill the bacilli, but, like anytin, has an action on the diphtheria toxin. Experiments on animals by Dr. Loeffler would indicate that the two preparations—cresol-anytole and anytin—may be advantageously employed in the local treatment of diphtheria, especially as they have little action on the mucous membranes.

There seems little doubt that these new preparations may be used with advantage in certain pathological conditions, but the evidence on this point cannot be regarded yet as complete. Further investigation is being conducted and clinical trials made. This series of compounds promises, at any rate, to be of great therapeutical interest.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

DEBATE OF THE "FIRST YEAR OF MEDICAL STUDY."

AN extraordinary Comitia of the Fellows of the Royal College of Physicians was held on May 12th, the President, Sir Samuel Wilks, Bart., being in the chair.

On the motion of the REGISTRAR the letter from the Medical School of Guy's Hospital read at the last meeting was referred to the committee of management.

Dr. W. R. Huggard, Dr. Oswald Browne, Dr. C. J. Arkle, Dr. J. Wiglesworth, Dr. F. Parkes Weber, Dr. H. J. Campbell, Dr. H. G. Turney, Dr. G. R. Murray, Dr. A. Newsholme, Dr. B. A. Whitelegge, and Dr. J. F. W. Tatham were admitted to the Fellowship.

The report of the examiners for the Murchison Scholarship was read, recommending that it should be awarded to Mr. J. Basil Page of St. Mary's Hospital. Mr. Page was then introduced and presented with the scholarship by the President.

The adjourned discussion on the proposal made by the committee of management to recognise as a year of medical study a year spent in the study of physics, chemistry, and biology at schools and institutions approved for the purpose was then resumed. The amendment, which had been moved by Dr. Payne and seconded by Dr. Pye-Smith, was:—"That the scheme proposed in the report of the committee of management be not adopted without a rigorous scrutiny of the list of institutions recognised for instruction in chemistry, practical chemistry, and biology."

The PRESIDENT having briefly stated the position, Dr. CHURCH said that anyone who had passed the required preliminary examination in general education was admitted on the Medical Students' Register of the General Medical Council if he were pursuing his scientific studies at one of the institutions recognised by the committee of management. In other cases, although the student might have received scientific instruction, he could not register until he had entered at a medical school. It was true, as Dr. Payne had said, that very few Scottish universities recognised such institutions and the University of Oxford did not recognise any. Dr. Church pointed out that there was a time when the teaching of these sciences was practically confined to medical schools, and the majority of the teachers were members of the medical profession. But it was very different now and, provided that there was satisfactory evidence that the means and facilities for such instruction were sufficient, there was no reason why it should not be given to students before entering on their medical course. He thought that this would be to the advantage of their hospital work, and he believed that the steps taken by the committee of management would secure that the teaching of science was of good quality.

The REGISTRAR explained the method adopted by the committee before placing any institution on the list of places recognised as properly equipped for this science teaching.

Dr. STEPHEN MACKENZIE supported the amendment, contending that the committee's proposal would deprive the student of the advantages secured by the five years' curriculum, diminish the period of his subjection to "collegiate influence," scatter his places of instruction, and conduce to cramming. It would also deprive him of the opportunity of dissecting whilst pursuing his scientific studies, whilst the medical schools would be still compelled to provide this science teaching for the higher examinations. It would be more logical for the medical schools to agree to cease to hold these classes and to relegate the subjects to preliminary education.

Dr. R. LEE, who doubted whether the General Medical Council had any legal power to register medical students, moved that the report be referred back to the committee.

Dr. J. K. FOWLER said that 12 out of 18 medical schools had supported the scheme of the committee. He pointed out that at present the able student was at a disadvantage, especially as under the former four-years' scheme it was found that the average time taken in preparing for qualification had been four years and nine months. The proposal would give the student four complete years of strictly medical study and would tend to give definiteness to the work of the first year at a medical school.

Dr. WASHBOURN seconded Dr. Lee's amendment, as it would enable the committee to put the regulations in a simpler form. He felt that anatomy and physiology should occupy at least two winter sessions and one summer session. It was important that the student should obtain his knowledge in the correct way and that the regulations and examinations should afford a safeguard against "cram."

Dr. Payne having withdrawn his amendment in favour of that proposed by Dr. Lee,

Dr. PYE-SMITH opposed the scheme, contending that it was not carrying out the spirit of the five years' curriculum, nor did he think it well that the medical student should be of the status of a schoolboy. He reminded the College that medical schools had made great sacrifices to equip and maintain admirably appointed laboratories and teaching staffs, on whom this proposed change would fall heavily.

Dr. COUPLAND would prefer the General Medical Council to be urged to postpone registration of medical students until these strictly preliminary scientific subjects had been passed. There would then be no longer need for the medical schools to provide instruction in elementary science, although of course ample scope existed for advanced instruction in these sciences as applied to anatomy, physiology and pathology.

Dr. PAYNE pointed out that the proposal of the committee was a new departure in its procedure. At present institutions are recognised as suitable for science instruction *before* registration, but now they were to be recognised as open to

students *after* registration. Was it seriously desired to make a board school a "medical school"?

Dr. NORMAN MOORE defended the procedure of the committee in recognising science schools and pointed out that whenever such recognition took place it was reported to, and sanctioned by, the College. The regulations of the examinations might be somewhat involved but they had to meet all exceptions to the general rule, nor was it desirable to be constantly changing them. The vast majority of the medical schools had approved of the proposed change. At present a student is encouraged to study physics, chemistry, and biology before entering at a medical school; he may pass the examination, but his five years' course only counts from the date of his entry at the medical school; in fact, he is in the same position as if he had deferred taking his science till then. And yet a student who passes the Preliminary Scientific (M.B.) Examination of London University can take his degree in four years. If the scheme were adopted the student would still have four complete years to enjoy the benefits of "collegiate influence." All that was proposed was that by recognising work at approved institutions carefully selected all students would be put on the same footing.

A division was then taken, when there voted for the amendment 17, against 30. The original proposition adopting the committee's scheme was then put and carried by a large majority.

The report of a special committee appointed on Oct. 28th, 1897, to consider the subject of elementary biology was then received, and its adoption was moved by Dr. GEE, chairman of the committee. A large number of teachers of the subject and school authorities had been consulted, and the committee recommended that in order that the time devoted to the study of biology should not encroach on that given to anatomy and physiology, the regulation for the second examination as to twelve months' dissection be modified by the addition of the following:—"This period of dissection must be subsequent to having received instruction in the subjects dealt with under sub-paragraph 2—(*a*) chemistry and physics and practical chemistry, and (*c*) elementary biology—in accordance with its regulations."

Dr. CHURCH seconded the motion, which was adopted, as was a further resolution to refer the report to the committee of management.

A communication was read from the Foreign Office, in reply to one from the President, on the subject of proposed legislative restrictions affecting foreign practitioners in Italy. The Marquis of Salisbury forwarded a copy of a despatch from H.M. Ambassador at Rome stating that the Italian Government do not contemplate any such change in the laws.

A communication was read from the Secretary of the Royal College of Surgeons of England enclosing a recent judgment of Mr. Justice Wright affecting the rights of the corporation.

Reports were read from the Finance Committee and from the Examiners for the Licence.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on May 12th, 1897, the President, Sir WILLIAM MAC CORMAC, Bart., being in the chair.

Mr. W. D. Spanton of Hanley, Staffordshire, was introduced, signed the by-laws, and was admitted a Fellow of the College.

Mr. Percy Furnivall, F.R.C.S. Eng., was introduced and the President handed to him the Jacksonian Prize with the document declaratory of the award.

The Chairman of the Library Committee reported that Mrs. William Hunter had, at the suggestion of Mr. Thomas Bryant, presented to the College 43 volumes of works on medicine, surgery, and anatomy which formed part of the library of her husband, the late Dr. William Hunter of Rothesay, N.B., and which originally belonged to Surgeon-General William Hunter. The best thanks of the Council were voted to Mrs. Hunter for her valuable donation to the library.

A motion was brought forward that the Council should authorise a special gown to be worn by the Fellows of the College. The principle was approved and a committee was appointed to consider and report as to the form.

It was unanimously decided that an appeal should be entered against the judgment of Mr. Justice Wright and Mr. Justice Channell on the payment of corporation duty by the College.

A letter was read from the committee acting for the Fellows and Members of the College who signed the petition claiming the right of electing the representative of the College on the General Medical Council; with it was forwarded a copy of protest against the recent decision of the Council in course of signature by Fellows and Members. The Secretary was directed to inform the committee that their letter had been laid before the Council.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Crewe Urban District.—Dr. Meredith Young, in presenting his first annual report, congratulates the Crewe sanitary authority on the completion of the new isolation hospital—which, by the way, he regards as having prevented a severe epidemic of scarlet fever during the last quarter of 1897. Dr. Young advises the erection of a refuse destructor and of a public abattoir, and he insists strongly on the necessity for putting an end to the numerous old privies, &c., which still obtain in Crewe by substituting for them the water-carriage system. We note in connexion with the isolation hospital that no cases of scarlet fever are sent home until all otorrhœa, rhinorrhœa, or albuminuria has ceased. This is an excellent precaution, but we fear that in some few cases the patient may have to take up a very prolonged sojourn in hospital. Desquamation is, too, we are told, carefully sought for on the scalp, this being a locality which is regarded as especially liable to be overlooked. The question, however, suggests itself as to whether a slight scurfiness on the scalp after scarlet fever can be considered as desquamation. Doubtless the scalp desquamates early in the disease, but after the peeling process has been followed from the head down to the feet and the feet have been seen to pursue the usual desquamative process we should hesitate to retain a child for an indefinite period owing to what might be termed a "branny" desquamation of the scalp. However, too much care cannot be exercised in discharging patients after scarlet fever and it is well to err on the safe side. We are glad to see that the parents of discharged children are told that the hospital authorities cannot guarantee that the patients are in all cases free from infection. This practice may be profitably carried out at all fever hospitals.

Bournemouth Urban District.—The water company which supplies Bournemouth with water has, Mr. Philip Nunn reports, always afforded him every facility for making any investigation and he regards the care and precautions taken by the company as eminently satisfactory. In October last he, together with the borough engineer and the engineer of the company, visited the filtering beds, reservoirs, collecting areas, and pumping stations, and it must be a source of satisfaction to the public to know that everything was then well protected against possible pollution. A somewhat unusual form of nuisance had to be dealt with during the year under notice in the shape of the carcass of a dead whale some 70 ft. long, which was left high and dry on the beach. After considerable delay 25 tons of flesh and offal were removed to the borough destructor.

Bilston Urban District.—The danger of introducing measles into a hospital devoted to the treatment of scarlet fever was well illustrated in Bilston during 1897. One boy who had been admitted on November 5th with scarlet fever contracted a fatal attack of measles three weeks later, and a girl admitted on November 18th suffering from scarlet fever died from measles on December 18th. Cases such as these show the importance of adequate small ward accommodation at a fever hospital and also the necessity of maintaining a staff of nurses to enable complications of this nature to be adequately dealt with. Dr. Ridley Bailey, when he became aware of these two cases of measles, very properly refused to

admit any more patients until the whole building had been thoroughly cleansed.

St. Marylebone Sanitary District.—Mr. Wynter Blyth expresses regret in his current annual report that the trade are colouring butter and margarine by aniline dyes, instead of, as formerly, by anatto or other vegetable colours of a harmless nature. It would, he thinks, be difficult to take action in the matter unless the colouring agent could be shown to be harmful in minute doses, or rather if an accumulation of such doses could be proved to be detrimental to the human economy.

St. Mary's, Stoke Newington, Sanitary District.—Dr. Henry Kenwood, in referring to the control of measles and whooping-cough through the agency of information derived from public schools, regrets that the regulation of the London School Board requiring the teacher to notify to the medical officer of health when a child is excluded on account of infectious disease should not be regularly carried out. In this connexion it might perhaps be well if provisions such as those contained in Section 57 of the Public Health (Scotland) Act, 1897, were made applicable and a parent or teacher were fined for knowingly permitting a child to attend school who has been suffering from infectious disease or who resides in a house where such disease exists or has existed within a period of three months unless such child produces a satisfactory certificate from the medical officer of health.

Liverpool Port District.—Dr. E. W. Hope reports that 3879 vessels were examined by the port sanitary inspectors during the year 1897 and on board of 2064 of these one or another sanitary defect was discovered. This seems a very large percentage, but perhaps the vessels examined were selected by virtue of there being a probability in favour of some insanitary condition. It would have been some guide in this sense had the total number of vessels frequenting the port been given. There were 63 cases of infectious diseases landed from vessels arriving in the port during the year, 27 of the cases being of enteric fever and 20 of measles; only 3 cases of small-pox were recognised. Amongst the non-infectious cases arriving in the port were 14 of beri-beri, 30 of dysentery, 242 of malaria, and 39 of tropical anæmia. As regards emigration, Dr. Hope states that the diminution which began in 1891 was still further marked during 1897, the total number, 87,414, being 10,865 less than in 1896.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6291 births and 3577 deaths were registered during the week ending May 14th. The annual rate of mortality in these towns, which had been 18·4 and 17·4 per 1000 in the two preceding weeks, further declined last week to 16·6. In London the rate was 15·7 per 1000, while it averaged 17·3 in the thirty-two provincial towns. The lowest rates in these towns were 10·0 in West Ham, 10·2 in Brighton, 11·7 in Cardiff, and 11·8 in Bristol; the highest rates were 20·0 in Plymouth, 21·8 in Manchester, 22·1 in Bolton and in Halifax, and 22·6 in Liverpool. The 3577 deaths included 383 which were referred to the principal zymotic diseases, against 468 and 408 in the two preceding weeks; of these, 133 resulted from measles, 115 from whooping-cough, 50 from diphtheria, 32 from diarrhœa, 27 from "fever" (principally enteric), and 26 from scarlet fever. No death from any of these diseases was recorded last week in Plymouth; in the other towns they caused the lowest death-rates in Portsmouth, Swansea, Nottingham, and Huddersfield; and the highest rates in Bristol, Norwich, Liverpool, and Salford. The greatest mortality from measles occurred in Bristol, Derby, Halifax, and Bradford; and from whooping-cough in Leeds, Sheffield, and Salford. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 50 deaths from diphtheria included 20 in London, 6 in Birmingham, 4 in West Ham, 4 in Cardiff, and 3 in Burnley. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in those hospitals and in the London Fever Hospital at the end of last week was 2246, against 2334, 2302 and 2271 on the three preceding Saturdays; 229 new cases were admitted during the week, against 241, 205 and 209 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 274 and 226 in the two preceding weeks, rose again last week to 232, but were 81 below the corrected average. The causes of 44, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Manchester, Salford, Leeds, and in sixteen other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the five preceding weeks from 24·2 to 21·7 per 1000, further fell to 19·8 during the week ending May 14th, but exceeded by 3·2 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·2 in Perth and 10·3 in Paisley to 19·6 in Dundee and 23·3 in Glasgow. The 325 deaths in these towns included 32 which were referred to measles, 26 to whooping-cough, 12 to diarrhœa, 6 to "fever," 4 to scarlet fever, and 3 to diphtheria. In all, 83 deaths resulted from these principal zymotic diseases, against 96 and 90 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2·8 per 1000, which was 1·0 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 35 and 27 in the two preceding weeks, rose again to 32 last week, and included 27 in Glasgow, 2 in Edinburgh, and 2 in Dundee. The deaths from whooping-cough, which had been 34 and 29 in the two preceding weeks, further declined to 26 last week, of which 17 occurred in Glasgow, 5 in Dundee, and 3 in Edinburgh. The 6 deaths referred to different forms of "fever" showed a slight further increase upon recent weekly numbers, and included 5 in Glasgow, where 2 of the 4 fatal cases of scarlet fever were also registered. Of the 3 deaths from diphtheria 2 occurred in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 137 and 129 in the two preceding weeks, further declined to 109 last week, and almost corresponded with the number in the same period of last year. The causes of 30, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·4 and 24·5 per 1000 in the two preceding weeks, further declined to 22·5 during the week ending May 14th. During the past four weeks the death-rate in the city has averaged 23·9 per 1000, the rate during the same period being 16·9 in London and 18·6 in Edinburgh. The 151 deaths registered in Dublin during the week under notice showed a decline of 13 from the number in the preceding week, and included 7 which were referred to the principal zymotic diseases, against 9 in each of the two preceding weeks; of these, 3 resulted from whooping-cough, 2 from "fever," 1 from diphtheria, and 1 from scarlet fever. These 7 deaths were equal to an annual rate of 1·0 per 1000, the zymotic death-rate during the same period being 2·0 in London and 1·9 in Edinburgh. The fatal cases of whooping-cough, which had been 3 in each of the two preceding weeks, were again 3 last week. The deaths referred to "fever," which had been 2 and 3 in the two preceding weeks, declined again to 2 last week. The mortality from scarlet fever and from diphtheria corresponded with that recorded in the preceding week. The 151 deaths in Dublin last week included 38 of infants under one year of age, and 35 of persons aged upwards of sixty years; the deaths of infants showed a further increase upon recent weekly numbers, while those of elderly persons showed a further decline. Seven inquest cases and 4 deaths from violence were registered; and 65, or more than a third, of the deaths occurred in public institutions. The causes of 14, or more than 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

HEALTH OF THE TIRAH FIELD FORCE.

DURING the late military operations on the North-West Frontier of India, extending from June 28th, 1897, to the break up of the Tirah field force in February, 1898, the maximum number of British troops employed at any one time numbered some 18,000. The very alarming reports as to the extent of invaliding appear to have been on a par with others *ad captandum vulgus*. Up to April 12th, 1898, only 489 men passed through Deolali invalided to England, including 106 from gunshot wounds and 163 from ague; 202 represent all other diseases. 44 of the latter were the results of dysentery, 29 debility, 19 enteric fever, 17 secondary syphilis, 14 remittent fever, 10 diarrhœa, 8 rheumatism, and only 2 from heat stroke, and 1 from bronchitis. The very low percentage speaks volumes for the endurance of the troops, for the sanitary arrangements made by all departments and for the treatment of the sick in the field and general hospitals of the army; the figures are in marked contrast to those of the Crimean period of forty years ago, when "light equipment" was in vogue *de rigueur*, and a veteran force of 27,000 men landed on Sept. 19th, 1854, without ambulances, field hospitals, or a trained medical corps, to be reduced at the end of two months to 11,000 men fit to carry arms.

NAVAL MEDICAL SERVICE.

Fleet-Surgeon George W. Bell to the *Crescent*. Staff-Surgeons: Alfred J. Pickthorn to the *Marathon;* William M. Craig to the *Galatea*, and John J. Dinnis to the *St. Vincent*. Surgeons: Shirley H. Birt to the *Crescent*, Arthur E. Kelsey to the *Collingwood*, lent to the *Devastation*, temporary.

ARMY MEDICAL STAFF.

The under-mentioned Surgeon-Captains are appointed to be Surgeon-Majors: Charles G. Woods and Henry T. Baylor. Surgeon-Major Hall has left Woolwich for Jamaica. Surgeon-Major Elderton has assumed medical charge of women and children, Marlborough Lines, Aldershot. Surgeon-Major Younge has arrived for duty in the Thames District, and Surgeon-Major H. J. Barratt has been posted to the Station Hospital, Canterbury, for duty.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel Alexander Crombie, M.D., Bengal Establishment, retires. The services of the undermentioned officers are replaced at the disposal of the Government of Bengal: Surgeon-Major Grainger (Bengal), Surgeon-Captain Brown (Bengal), Surgeon-Captain Green (Bengal), Surgeon-Captain Moir (Bengal), and Surgeon-Captain Stevens (Bengal). The services of Surgeon-Major Cunningham (Bengal) are replaced at the disposal of the Government of the Punjab. The services of Surgeon-Major Pemberton (Madras) are replaced at the disposal of the Government of Madras. Surgeon-Lieutenant-Colonel McCloghy and Surgeon-Captain Arnim have respectively delivered over and received charge of the office of the Deputy Sanitary Commissioner, Sind Registration District. Brigade-Surgeon-Lieutenant-Colonel Sir. A. S. Lethbridge, K.C.S.I., and Brigade-Surgeon-Lieutenant-Colonel D. D. Cunningham, C.I.E., receive the two extra pensions of £100 each available for the Bengal Medical Establishment for the year 1898–99, and Brigade-Surgeon-Lieutenant-Colonel F. H. Blenkinsop and Brigade-Surgeon-Lieutenant-Colonel J. Arnott the pensions due to the Madras and Bombay Establishments respectively.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant H. E. Mortis to be Surgeon-Captain.

VOLUNTEER CORPS.

Royal Engineers: 1st Middlesex: Surgeon-Major R. M. P. Low, M.B., resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. *Rifle:* 1st Volunteer Battalion the King's (Liverpool Regiment): Keith Waldegrave Monsarrat, M.B., to be Surgeon-Lieutenant. 1st (Exeter and South Devon) Volunteer Battalion the Devonshire Regiment: Ransom Pickard, M.D., to be Surgeon-Lieutenant. 3rd Lanarkshire: Surgeon-Major A. Napier, M.D., to be Surgeon-Lieutenant-Colonel. 1st Cinque Ports: Henry James Holman to be Surgeon-Lieutenant. 5th (West) Middlesex: Charles Arthur Goulett to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: William Bridgett Pritchard to be Surgeon-Lieutenant.

THE SPANISH-AMERICAN WAR.

Notwithstanding that the newspapers devote columns to the subject of the war between Spain and the United States there is really little or nothing to be chronicled in the way of reliable or important news. With Admiral Cervera's departure with his Spanish squadron from Curaçao we, like the squadron, are simply at sea, the only difference being that the Spanish Admiral knows whither he is going and why and we do not! Attempts will be made by the American fleet to intercept him, but it is simply a matter of conjecture whether they will be successful or not, or when and where the big naval battle alleged to be looming in the near future will take place, or even whether it will occur at all. It seems clear that the Americans have for the present, as we surmised would be the case, relinquished the idea of sending a large force to Cuba as impracticable, on account of the transport and sanitary difficulties in the way. The United States must have command of the sea before doing so, as probably no one knows better than Captain Mahan himself. It will in the meantime subject the naval, military, and medical authorities of the States to a great strain to equip and transport the large land force required by Admiral Dewey for the occupation of Manila. A large hospital and sanitary service will be required to accompany the force proceeding there, for the Americans are quite alive to the fact that there may be much inefficiency from sickness among the troops for whom adequate preparations will have to be made.

THE ROYAL MILITARY TOURNAMENT.

The opening of the Royal Military Tournament at the Agricultural Hall, Islington, was preceded by a private rehearsal and luncheon on Wednesday last, May 18th. As we announced last week the pageant this year is called "Shoulder to Shoulder" and is representative of the sister services who fought side by side at Cadiz in 1596 and at Gibraltar, Alexandria, and El-Teb at periods between 1704 and 1884. Those who are responsible for the arrangement of this excellent spectacular performance certainly deserve the appreciation which the audience showed with regard to this part of the programme. The inclusion of Piper Findlater among the *personnel* of the pageant was a happy idea. The ever-popular musical ride by the Royal Horse Guards (the Blues) was received with hearty applause, as was also the musical drive by G Battery of the Royal Horse Artillery. In this some new and daring movements have been introduced. The displays by the Army Gymnastic Staff and class of non-commissioned officers under instruction at the Gymnasium, Aldershot, were well received. The rehearsal included tent-pegging, jumping, the *melée*, &c., and concluded with a realistic representation of the capture of Benin. That the present Tournament will be a success there can be no doubt.

SOLDIERS' AGES AND FLAT OR DEFORMED FEET.

With regard to the alleged and actual ages of recruits and young soldiers we can understand that, according to a recent War Office Order, a commanding officer has to determine the point in consultation with a medical officer as to whether there are sufficient physical signs present for believing a man to have really reached the age of nineteen years; but as regards another ruling we confess we do not quite appreciate the force of it. The Secretary of State for War, we are told, has had his attention drawn to the number of men invalided from the army on account of flat or deformed feet. In future such men are to be sent to the gymnasium to see whether the physical defect cannot be remedied or improved by a suitable course of physical exercise. Assuming that the case be really one of flat or deformed feet we are very sceptical about the removal of the defect by this means. It depends of course upon its nature and extent whether improvement can be effected in this way—especially at a soldier's age. Care in examining recruits and attention to the careful fitting of soldiers' boots strike us as a more likely method of overcoming the evil.

DEATHS IN THE SERVICES.

Staff-Surgeon Josiah Austen, on May 2nd He was appointed surgeon in the Navy in 1852 and was promoted staff-surgeon in 1861.

Surgeon-General James Irvine, Bengal Army (retired), on May 3rd, at Clifton, Bristol, in his seventy-sixth year.

THE LATE INDIAN FRONTIER WAR.

Everything remains quiet on the frontier and in the Khyber. Some sickness is reported, however, among the British troops at Jamrûd and Bara.

Surgeon-Major-General S. A. Lithgow, M.D. Edin., C.B., D.S.O., has been selected for the appointment of honorary physician to the Queen, rendered vacant by the death of Surgeon-General S. Currie, M.D. Edin., C.B. Surgeon-Major-General Lithgow was appointed to the army in February, 1855, and during his long service has been several times on active service in the field, including the Indian Mutiny, 1857–59. He took part in the Soudan Expedition of 1884–85 on the Nile and was principal medical officer on the lines of communication. He was mentioned in despatches, received the medal and clasp, and was created a C.B. He was again in the Soudan in 1885–86 and was mentioned in despatches and received the Distinguished Service Order. In 1890 he took part in the operations of the Zhob Field Force in India and was again mentioned in despatches.

Surgeon-Major A. C. A. Alexander, Coldstream Guards, is the Principal Medical Officer in charge of the Royal Military Tournament at the Agricultural Hall, and he is assisted by Surgeon-Captain G. W. Tate, M.B., A.M.S. Veterinary Major Rowe, A.V.D., is in charge of the horses.

Correspondence.

"Audi alteram partem."

THE PROSECUTION OF REGISTERED PRACTITIONERS BY THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—The recent prosecution by the General Medical Council of Mr. H. K. Hunter, L.S.A. Lond., of Gamlingay, Cambridgeshire, for assuming the titles "Physician and Surgeon" must have come as a surprise to most members of the profession. It undoubtedly seems strange that the Council should use its funds in prosecuting a registered medical practitioner whilst hosts of unqualified persons are permitted to practise medicine and surgery with impunity. After reading the report of the case of the proceedings in the *Times* of April 8th last I communicated with the Registrar of the General Medical Council, asking for information as to who ordered the prosecutions, as I had no recollection of the facts of the case having been brought before the Council. From him I learnt that the General Medical Council, when *in camerâ* on Nov. 25th of last year, directed, on the recommendation of the Penal Cases Committee, the prosecution under Section 40 of the Medical Act of 1858 of certain persons, amongst whom was Mr. H. K. Hunter.

I shall feel obliged if you will permit me to state in your columns that I had not the slightest idea that the name of a registered practitioner was among those recommended for prosecution by the Penal Cases Committee. I was under the impression that the persons reported upon by the committee were those only whose names had already been removed from the Medical Register and still continued to practise and use medical titles. Had I known that the name of a registered practitioner was included in the list I should have dissented from the recommendation. I have reason to believe that many of the other members of the Council—the Penal Cases Committee excepted—were likewise ignorant of the fact that Mr. Hunter was a registered practitioner. This, however, I freely confess does not relieve us of our responsibility as being parties to the action. We ought not to have assented to the recommendation of the Penal Cases Committee without having had all the facts of each case before us. That the Council should have been placed in such an unfortunate position indicates that our methods of procedure are faulty. Instead of referring cases reported to the Council for prosecution to a small committee, it would, in my opinion, be far better that the cases should be considered by the Branch Council for the division of the kingdom in which the persons complained of practise. It is therefore my intention at the forthcoming session of the Council to propose that the Penal Cases Committee be not reappointed, and that penal cases be hereafter referred for consideration and report to the respective Branch Councils. Should this proposal be adopted we may hope that the law officers of the Council may not again be called upon to prosecute a registered practitioner under similar circumstances.

I am, Sirs, yours faithfully,

GEORGE BROWN,

Direct Representative for England and Wales.

Gibson-square, Islington, N., May 17th, 1898.

"A METHOD OF EXPOSING AND OPERATING ON THE KIDNEY WITHOUT DIVISION OF MUSCLES, VESSELS OR NERVES."

To the Editors of THE LANCET.

SIRS,—A few days ago I read in a paper by Joseph Price a quaint sentence which accurately describes a good deal of what is published now: "Frequently some one of our medical or surgical brothers comes running out of the bushes crying, 'I have found something.' It is usually a bug, an antitoxin, or a new method."

I can neither confirm nor correct Mr. Mayo Robson's statement that Mr. Greig Smith approved of the principle of exposing the kidney without cutting muscular fibres, but as I taught him to open the abdomen by splitting open the muscular sheath and separating the fibres of the *rectus* I have no doubt he also approved of and practised what I also taught him, to open the loin similarly, whether operating on the kidney or the colon, by what Mr. Mayo Robson believes is a new method. If its history is a matter of importance then I ought to put it on record that I was taught it in Edinburgh by the late McKenzie Edwards as the best way to imitate a sphincter in colotomy thirty-five years ago and that I have practised it uniformly ever since, with an incision, I should say, about one-third the size indicated by Mr. Mayo Robson.

I am, Sirs, yours faithfully,

Birmingham, May 14th, 1898. LAWSON TAIT.

"THE DANGER OF ASPIRATING THE LIVER."

To the Editors of THE LANCET.

SIRS,—Surgeon-Lieutenant-Colonel Hatch, I.M.S., has done well in drawing attention in the *Indian Medical Gazette* for April, 1898, to the possibility of aspiration of the liver producing a fatal hæmorrhage into the cavity of the peritoneum. This important fact is but little known and has been seldom referred to in writings on the treatment of liver abscess. Surgeon-Lieutenant-Colonel Hatch recommends caution in the operation of aspiration of the liver for diagnosis of abscess; but you go further and state that "the operation offers no advantages to compensate for its undoubted risk" and recommend its total disuse.[1] This view will not, I believe, commend itself to the majority of surgeons and, if adopted, will result in patients dying from liver abscess unrelieved because their condition remains undiagnosed. The advantages of the operation are the certainty of diagnosis as to the presence of an abscess and its position if a positive result be obtained, and its almost certain absence if pus be not reached on the insertion of the needle at three or four situations. The books notwithstanding, there are no symptoms or physical signs on which the surgeon can depend for indicating the necessity of operation in cases of suspected abscess of the liver; perhaps of the latter œdema of the skin is the most valuable, but it is very seldom apparent, not oftener than in 4 or 5 per cent. of the cases—a sense of fluctuation may be left out of consideration, as it is hardly ever perceptible. I have discovered by means of aspiration liver abscess in cases where the classical symptoms of this complaint were all absent, and where only pain over the liver and the patient's history warranted a bare suspicion of its presence, and I have found it on post-mortem examination in cases which during life exhibited no sign of it. Probably no disease presents cases in which diagnosis is more difficult than it is in some

[1] THE LANCET, May 14th, 1898, p. 1343.

cases of liver abscess, and in these "prospecting" the organ with an aspirator affords the only certain data on which to form an opinion. I have treated a large number of cases (over 150) in which abscess of the liver was present or suspected, and my routine plan has been to aspirate first at one or more points and then to operate on a positive result being obtained. In those cases in which pus was not reached no evil effect was ever perceived, the only result being a very considerable decrease of the pain previously felt, and this whether the amount of blood removed was great or small. The needle employed should no doubt be small, and that it be too narrow to permit the pus to flow freely, through it in some cases is hardly an objection, because even under these circumstances sufficient for merely diagnostic purposes may be obtained on separating the needle from the indiarubber tube and blowing its contents on to the palm of the hand.

In the face of the cases related by Surgeon-Lieutenant-Colonel Hatch and of others one must admit a certain amount of risk from aspiration of the liver, but the ratio of fatal cases to the total number treated is almost infinitesimal and should be disregarded. The fact that THE LANCET is read all over the world by medical officers who are likely to have these cases to treat must be my excuse for asking you to give space to this letter.

I am, Sirs, yours faithfully,

W. F. STEVENSON, Surgeon-Colonel A.M.S.,
Professor of Surgery, Army Medical School.

Netley, May 15th, 1898.

THE POLICE AND THEIR AMBULANCE ARRANGEMENTS.

To the Editors of THE LANCET.

SIRS,—The Home Secretary's reply in the House of Commons to a question about first aid in London, as reported in THE LANCET of May 14th, seems to me to deserve more attention than it has yet met with at the hands of the press, since it affects in a marked degree the safety of all those who daily pass along our thoroughfares. With reference to the ambulance work rendered by the police on the occasion of the collapse of a building in Westminster on April 21st the following undisputed facts may be noted. No first aid was rendered on account of "the presence of a great and excited crowd" (springing up, I suppose, instantaneously); cabs were used to convey the injured to the hospital, for there could be no time to get any other means of conveyance, as they were removed to the hospital and under treatment within four minutes of the accident. Out of the 70 constables present who, we are told, were competent to render first aid not one was called upon to treat a single case.

It is superfluous on my part to comment upon the curious reason given by the police for not rendering first aid or upon the hasty method of getting these poor injured men to the hospital, as both are exactly upon all fours with the ordinary manner adopted by the police in treating the every-day accidents in our streets. They only bring out in strong relief the main fact that no ambulance work of any consequence is carried out by the police in the case of street accidents. If ever there was a case in which first aid ought to have been promptly rendered the catastrophe at Westminster was the one and it is not creditable to this city that the police ambulance arrangements should turn out to be such a failure.

I am very much afraid that the remarks of the Home Secretary were not thoroughly understood by the House of Commons or the Members would never have cheered the admission that no first aid was rendered in a case where it was so essentially required. Surely the time has now arrived when the Government should make some attempt by inquiry or otherwise to discover what is wrong and why we cannot have some more efficient system of first aid employed in our streets. During this year, judging from previous statistics, I estimate there will be 12,000 accidents in the streets of London (including the City), and, as you have stated elsewhere,[1] these only form a small portion of the cases which would require assistance and I ask, therefore, in the name of humanity, the suffering humanity that is before our eyes, whether you cannot do something to draw the attention of the Government to this crying want. Your power is great and could hardly be used in a better cause.

I am, Sirs, yours faithfully,

HEATON C. HOWARD.

[1] Hospital Sunday Fund Supplement, May, 1895.

THE VICE-PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

To the Editors of THE LANCET.

SIRS,—I desire to intimate through the columns of THE LANCET that I have relinquished the intention which I had formed to seek the Vice-Presidency of the Royal College of Surgeons in Ireland at the approaching election in June next. When I expressed to the Fellows my determination to offer myself for that office I felt that my long service to the school and College as an examiner and Councillor and my seniority as a surgical teacher and as a hospital surgeon might reasonably deserve recognition by the Fellows and that I might hope to be honoured with election to the office which I seek. Unhappily, personal and domestic circumstances prevented me from giving prominence to my candidature until others had occupied the ground in some degree, and as a contest is extremely distasteful to me and in my opinion is not to the advantage of the College I have thought it best to refrain from presenting myself for the vice-chair until the next vacancy may occur. I desire, however, to assure the Fellows that under any circumstances I shall do so when that time arrives and that meanwhile I shall hope to retain my seat on the Council, for re-election to which I now offer myself. With this assurance before them I trust that my friends and supporters will not be induced to pledge their votes to any other candidate for a succeeding vice-presidency.—I am, Sirs, yours faithfully,

L. HEPENSTAL ORMSBY, M.D. Dub., F.R.C.S. Irel.

Merrion-square, Dublin, May 16th, 1898.

"THE DIPLOMA OF THE APOTHECARIES' SOCIETY."

To the Editors of THE LANCET.

SIRS,—Whilst agreeing with Dr. Bateman that Mr. Victor Horsley is an admirable Direct Representative, and likewise agreeing in some degree with his remark as to the "unwisdom of the prosecution" of the L.S.A. London for assuming the title "Physician and Surgeon"—as after all said there is scarcely more than a technical distinction between the L.S.A. and multitudes of others who adopt the same title—be it said to the credit of the General Medical Council, however, that they have got on the right scent, as an intolerable amount of snobbism exists at the present day with regard to the use, or rather abuse, of this title. Until a comparatively recent date this kind of braggadocio was confined to the slums, whereas now the infection has spread to innumerable refined and suburban localities. One of these I happen to know where three medical men, respectively graduates of a university, have in addition to the ordinary plate representing their qualification another plate underneath especially limited to the title, "Physician and Surgeon"; and as to another instance I know an M.R.C.S. and L.R.C.P. Edin. who, in giving a testimonial in a local paper, inserted "Physician" after his name, ignoring altogether the "Surgeon."

I am, Sirs, yours faithfully,

London, May 15th, 1898. M.R.C.S., L.R.C.P. EDIN.

THE MILITARY HOSPITAL AND SANITATION AT CADIZ.

(FROM OUR SPECIAL CORRESPONDENT.)

IN face of the trouble which is besetting the whole Spanish nation it is hard to criticise severely the shortcomings which unfortunately are but too evident. As Cadiz is the nearest Spanish port to Cuba and America I naturally imagined that the town would be in a state of feverish activity. I have nothing to do with the military aspect of the question, but from the sanitary point of view Cadiz is the natural landing place for the sick and

wounded from the seat of war. Consequently I imagined that members of the Red Cross fraternity would be seen everywhere making extensive preparations, and my first care on reaching Cadiz was to call on the president of the local Red Cross Society. My consternation may, however, be better imagined than described when I was told very quietly that the association did not exist as an active body in times of peace. This was April 25th, and that same evening it was proposed to hold a meeting to see if anything could be done. Naturally it is now too late to do anything which will be really effective. As the Red Cross Society was in this passive condition I imagined that in any case the ordinary military services would be in active working order. Consequently I went to the military hospital, but here also I found the same state of stagnation—indeed, it was all so bad that I felt quite discouraged and incapable of entering into details. Here and there a ward was shown to me as being "a little better," and in a yard there were a few men engaged digging up the earth for the purpose of laying a drain which it was imagined would remove some of the stench arising from the latrines. But the drain was a square brick drain and therefore is likely to contaminate the surrounding subsoil and cannot, by reason of its shape, be self-cleansing. On all sides in the building there were rafters and angles and dusty corners. The one redeeming feature is the fact that there is some open ground and some old structures are being demolished. Also just outside the hospital the construction of a large theatre has been commenced and abandoned. The roofless walls would make a fine enclosure and give shelter from the wind in cold weather and shade in hot weather. This would be an excellent place for the erection of tent hospitals. The one thing to be done is to evacuate all, or nearly all, the wards. Then all the open spaces should be utilised to establish tent hospitals. Place the wounded under canvas and then they will enjoy efficient ventilation. All the existing drains and closets should be closed up after pouring down the greatest possible quantity of disinfectants. The tent hospitals should be provided with portable earth closets; the soil to be removed and fresh earth supplied every day. By thus saving the patients from the hospital, camping them out in the open air, and breaking off all connexion with existing drains some hopes could be entertained of their recovery. What is, however, so wonderful is the fact that some of the patients actually recover in spite of the insalubrious condition of this military hospital. Such a fact speaks volumes in favour of the Spanish soldier. He is so abstemious, so steady, so sober, that it is very difficult indeed to kill him. British troops would die in such a hospital, but some, at any rate, of the Spanish soldiers survive. It is impossible not to admire these patient, all-enduring soldiers, but is it right to take advantage of these qualities and make their wonderful vitality an excuse for gross neglect? During the siege of Paris in 1870–71 it was found that the best results from operations, the fewest cases of blood-poisoning, &c., occurred at the American ambulance and this was an ambulance established under canvas. In spite of the Siberian winter which then prevailed the wounded who were nursed under canvas prospered and there were a greater number of recoveries at the American ambulance than at other ambulances where the wounded were treated within the walls of houses. Now, in the poverty-stricken condition of Spain it is useless to propose the building of model hospitals. Besides, even if the means were found for such, hospitals could not be built in time to be of service for the present war. On the other hand, tents are cheaper and can be erected rapidly. Also, in the event of a bombardment, a shell falling on a tent hospital would not do as much mischief as if it fell on a hospital of stone or brick. Now, according to certain telegrams, it would seem as if a naval engagement might take place near Cadiz. This may be followed or accompanied by a bombardment of the town. The danger rests in that case with the splinters as well as with the shell. A wall is of no use against a shell; the fragments of the masonry only add to the number of the splinters. The resistance which the wall offers causes the shell to burst; but a shell would pass through the canvas of a tent without bursting. If, however, a shell bursts outside a hospital then a masonry wall is of use in sheltering the patients and attendants from the fragments. Consequently a tent hospital surrounded by walls represents perhaps the ideal of safety if the walls are not too near to the tent. The shell striking the wall placed at a little distance from the tents bursts in the wall and no one is hurt. If the shell does not strike the wall it may pass through the tent, but without bursting, and would therefore cause no damage unless it happened to hit someone, which is the lesser probability. The danger is due to the numerous fragments rather than to the unexploded and entire shell. In view of these considerations, and as it is absolutely impossible to rebuild the Cadiz military hospital in time to be of service during the present war, the one thing to be done is to establish tent hospitals in the surrounding open spaces and to put the patients under canvas. In so beautiful a climate as that of Andalusia this would be no hardship and financially this would also be the very best way out of the difficulty.

As for Cadiz itself, the town consists of a number of narrow, ill-drained streets. An elaborate plan for the drainage of Cadiz was prepared in 1893. It has remained in the pigeon holes of the municipality ever since. There I found it neatly packed in cardboard with red ribbon bows. It looked very pretty and doubtless it is a very good scheme, but it will be time to discuss its merits when there is a serious prospect of its being carried out. Moreover, I was not able to meet with anyone who seemed capable of giving me a clear account of what it was proposed to do, and from all I heard and saw I was convinced that Cadiz would remain in its present insalubrious condition for some time to come. Of this unwholesome state of affairs I had ample opportunity of judging, for there had been a storm and the sewers, under the pressure of the water, emitted the foulest odours all over the town. It seemed as if hundreds of cesspools were being emptied simultaneously and, as bad sewers are little better than cesspools, the storm waters were actually performing some such Augean task. Yet, notwithstanding all this, when the storm was over the air became so limpid, the sky and waters so blue, that all nature seemed to smile with peace and plenty. Fruits and flowers abounded on all sides and the orange blossoms and bushes of heliotrope, were so bright and sweet that they soon made me forget the stench of the overloaded sewers. But a little care, a slight knowledge of the elementary principles of hygiene and their practical application to everyday life, and what a perfect and ideal town such a place as Cadiz would become. To think that there should be so much foulness, such filth and bad sanitation just where Nature shows herself in all perfection. Let us hope that that drainage scheme, so carefully tied up with red ribbon, will not slumber very many years more in the archives of the Cadiz *Ayuntamiento*.

Cadiz, May.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Outbreak of Plague in Calcutta. — Lessons of the Plague.—Increase in Kurrachee.—The Plague among Rats.

NOTWITHSTANDING the attempts of the authorities to keep undeclared the cases of plague in Calcutta the outbreak is now unmistakeable. The occurrence of the disease in the metropolis of India is a national calamity, because it seems almost bound to spread not only throughout the city itself but among the 80,000,000 people inhabiting Lower Bengal. The conditions of life of the great mass of the people are very similar to those of the people in Bombay and the natives live among equally insanitary surroundings. The mortality from plague in Bombay during the eighteen months of its visitation may be put down at one fortieth of the population, and the ratio of mortality among those attacked averages nearly 75 per cent. Bombay, therefore, has not suffered severely compared with the results of epidemics elsewhere, but the damage done to trade has been enormous. This injury has in all probability been greatly increased by the adoption of a system of quarantine—a system which has over and over again been condemned and which has once more been found to be valueless. The plague in Bombay has also taught other lessons. It has been found that the discovery of cases is most difficult notwithstanding the house-to-house visitation and the other measures adopted to obtain this result. If, therefore, notification be so imperfect the isolation of a percentage of plague cases only must cause this measure to fall very far short of completeness. Segregation of "contacts" again being dependent upon the other

measures must be still less successful. These lessons from the plague in Bombay have been learnt by the authorities in Calcutta and it has already been intimated that the severe repressive measures carried out by the Plague Committee in Bombay will not be adopted. Emptying infected houses and giving the occupants the option of inoculation or segregation promise a much better hope of success. The benefits of inoculation cannot now be disputed, and while for many reasons anything like compulsory inoculation should not be introduced, yet very considerable pressure can be exercised to further its adoption. If it be brought directly home to the minds of the people that it is less than the other evils of repressive sanitary measures the people will probably agree to it. This can be done by giving to an inoculated person the privilege of unrestricted freedom. Such a course would not only tend to make inoculation popular but must prove of immense benefit in many other directions.

The plague in Bombay city itself is rapidly on the decline. Some of the outlying districts prevent the mortality falling to its normal limits. There is reason to believe that the death-rate from so-called fevers is distinctly lowered in the presence of plague. The lowered birth-rate in Bombay, as well as in Poona, during the plague outbreaks is explained by the exodus of women to surrounding districts. In the Punjaub and in Kurrachee the disease seems to be spreading considerably. In the latter city from 30 to 40 fresh cases are being discovered daily. The mortality is very high. Some of the English medical men and nurses have recently been sent to give urgently required assistance and a large staff of practitioners and nurses are about to leave for Calcutta in anticipation of the great demands likely to be made upon their services. These recent outbreaks in Kurrachee and Calcutta, as well as the extension of the epidemic in other districts, conclusively show that the advent of the hot season has little influence in restraining the virulence of this disease. It occurs on high ground as well as at the level of the sea, on dry ground as well as in towns which are more or less waterlogged, in hot weather as in winter, and in the wet season as at other times of the year. The coincidence of the disease occurring in the rat at the commencement of an outbreak among human beings is the one prominent factor amongst the observed associated phenomena.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Deaths under Chloroform.

A CASE of death under chloroform occurred at the General Hospital on May 3rd and was subsequently the subject of an inquiry by the coroner for the city. The patient was a child, aged ten years, the operation being for an affection of the nose and throat. Dr. Sidney Haynes in his evidence stated that he had examined the child previously and had found no contra-indication to the use of chloroform. He had administered it in about 6000 cases and this was the first death which had happened under his care. The coroner (Mr. Bradley) in addressing the jury said that according to a medical paper he had before him there appeared during the last few years to have been an alarming increase in the number of deaths taking place whilst patients were under anæsthetics. In 1887 the number of deaths was 16, whilst in 1897 they reached 96. The jury returned a verdict to the effect that the deceased died whilst under an anæsthetic which was properly administered. At the same time they thought that in such cases parents should be informed that an anæsthetic was proposed to be used and their consent in writing should be obtained. The question was considered by the medical committee of the hospital subsequently. The number of deaths occurring in the hospital was stated to have been in 1892, 1; in 1893, 2; in 1894, 2; in 1895, 2; in 1896, none; in 1898, 2—in the first three months of the year. Obviously the number of operations in which anæsthetics are administered should be considered in any statistics of this kind. Letters have been written to the daily press upon the subject by medical men, a form of discussion to be deprecated and one calculated to raise undue alarm in the public mind. The medical committee have taken the wisest course in appointing a sub-committee to inquire into the whole subject of purity of the anæsthetic used, the dosage, and the conditions generally affecting the issue.

Boric Acid and Butter.

A prosecution by the Birmingham Corporation was conducted at the police-court on May 10th against a tradesman for selling butter containing boric acid. Half a pound of the butter which had been purchased contained boric acid at the rate of 70 gr. to the pound. Dr. Hill, the public analyst, stated that boric acid had powerful physiological effects; it created irritation of the stomach, was a depressant of the heart, and produced congestion and sometimes hæmorrhage of the kidneys. Out of 37 samples of food which he had analysed twelve months ago 20 were adulterated with boric acid. Dr. A. P. Luff, analyst to the Home Office, said that he was decidedly of opinion that 70 gr. of boric acid to the pound in butter would be noxious to health. A fine of 20*s.* and costs was imposed, the costs to include £5 towards the expenses of the prosecution. The question resolved itself into one of amount. Can 1 per cent. of boric acid, as in this instance, be looked upon as excessive, so as to be injurious to health? The Bench decided in the affirmative, and whatever the effects of this dose might be in the quantity of butter eaten they showed that the adulteration could not be effected without breaking the law as they interpreted it on this occasion.

Extraordinary Deaths.

On May 11th, an inquest was held at Dudley on the body of a woman aged sixty-five years, who met with her death in an exceptional manner. After kneeling at the grave of her brother in the cemetery she made an effort to rise, but in doing so fell into the vault over which she was kneeling and disappeared from view; when taken out she was dead. Her weight was 16 st. 12 lb., the vault was from 8 to 9 ft. deep. On May 4th an inquest was held on the body of a woman, aged thirty-three years, the subject of delusions. The deceased was found on the floor of the house dead, her clothing saturated with water, and a pool of water around. There was nothing found to account for her condition. The canal was a quarter of a mile away. The medical man who made the post-mortem examination said that he came to the conclusion that the deceased had died from asphyxia caused by water—practically drowning. He added that according to an American authority a case was recorded where a person who had been immersed in water had recovered sufficiently to walk a considerable distance and had then died. From the condition of the deceased's body and clothing he thought that she had been completely immersed in water. The jury found that death was due to drowning but that there was no evidence to show how the drowning was caused—a conclusion which must be viewed as exceptional in the history of deaths from drowning.

May 17th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Farewell to the late Principal of University College, Liverpool.

THE leave-taking of Dr. G. H. Rendall, the late principal of University College, Liverpool, which took place on May 6th in the Arts Theatre of University College, was a highly interesting ceremony. The Earl of Derby, the president of the college, took the chair on the occasion and the meeting was also graced by the presence of the Lord Mayor of Liverpool and the Lady Mayoress; members of the college council; members of the senate and professorial staff, among which the medical element was largely represented; and also by numerous prominent citizens. Eulogistic references to the many high qualities possessed by the late principal were made by the Earl of Derby and Mr. E. K. Muspratt, the vice-chairman of the council of the college. Not the least interesting feature of the ceremony was the address presented to Dr. Rendall by the students' representative councils on behalf of the male and female students of the college. The president asked Dr. Rendall to unveil a medallion memorial to the late Mr. George Holt, a great benefactor of the college. The public farewell to Dr. Rendall was concluded by a banquet in the evening at the Adelphi Hotel, which was again presided over by the Earl of Derby. The company was large and representative and the

proceedings passed off in the most harmonious manner. The toast of "Victoria University" was proposed by Ian Maclaren (the Rev. Dr. Watson) in a felicitous speech, and was replied to by Principal Boddington, vice-chancellor of Victoria University.

Death of Mr. David Garnet Hurter, M.B., Ch.B. Vict.

The death of Dr. D. G. Hurter at the Liverpool Royal Infirmary on May 11th from typhoid fever, contracted while actively engaged in the discharge of his duties as house physician, cast a gloom over the entire hospital and medical school. Only in July last had young David Hurter obtained honours in the final examination for the M.B. Vict., and his subsequent work in the hospital fully bore out what his student life had shown him to be—a man of original mind and tireless industry. Born in 1875, he was educated in Switzerland and subsequently in Liverpool, joining the Liverpool Medical School in 1892. Among the distinctions obtained during his student career were gold medals in anatomy and medicine, a silver medal in forensic medicine, and certificates of honour in physiology and physics. In October last he was appointed house physician at the Liverpool Royal Infirmary, as stated in THE LANCET, and only last month he was appointed house surgeon, a post he was unhappily never destined to hold. On Sunday, May 15th, a memorial service was held in the chapel of the Royal Infirmary, which was numerously attended by the members of the staff and many of the deceased's colleagues and friends, by all of whom his early death is deeply lamented.

Death of Mr. Thomas Gordon, M.A., M.D. Edin.

The death of Dr. Thomas Gordon, which occurred on May 11th from typhus fever after an illness of ten days, came as a great surprise to his numerous friends and patients. Dr. Gordon graduated at the University of Edinburgh in Arts and Medicine. He was the youngest son of the late Mr. John Gordon of Montrose, N.B., and after practising for a short time in London removed to Broadgreen, near Liverpool, eventually settling down in Liverpool. The deceased was well known in golfing circles. How and where he contracted the illness which resulted in his death at the age of forty-five years has been a matter of anxious investigation on the part of the health authorities.

Ladies' Charity and Lying-in Hospital.

The vacancy in the outdoor medical staff of the Ladies' Charity and Lying-in Hospital has been filled by the appointment of Dr. William Tweedale Thomson, a graduate of the University of Edinburgh.

Hospital for Consumption and Diseases of the Chest.

Messrs. Lockett have contributed the sum of £100 towards the new building fund of this charity.

A Female Registrar of Births and Deaths.

The West Derby Guardians have recently appointed Mrs. Richard Edwards, wife of the retiring registrar, to the post of registrar of births and deaths for the Litherland district.

Presentation to Mr. Charles Langton by the Hospital Saturday Fund Committee.

An interesting gathering was held on the 14th inst. at the Liverpool Royal Infirmary to witness the presentation of an illuminated address subscribed for by the committee of the Hospital Saturday Fund to Mr. Charles Langton upon his retirement owing to ill-health from the post of chairman, an office which he had held for many years. Mr. Langton has devoted his life to hospital work. If not the oldest he is one of the oldest members of the committee of the Liverpool Royal Infirmary. He has been chairman of the Nurses' Home in Dover-street, and for many years has been a member of the committee of the Children's Infirmary. Mr. Langton in a graceful speech thanked the committee of the Hospital Saturday Fund for the good feeling they had always evinced towards him whilst he was their chairman.

May 17th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Title of Doctor of Medicine.

THOMAS PAINE HETHERINGTON was on May 13th prosecuted before the Mayor of Newcastle-upon-Tyne and other magistrates for illegally using the title of Doctor of Medicine. For many years this man has been making a considerable income by holding himself out as a specialist in the treatment of venereal disease. His defence was that he was registered as a dentist and a doctor of medicine of the United States of America; that his father and grandfather had both carried on the same trade in Newcastle without interruption; and that he did not charge for advice, only for medicine supplied, which he said he had a licence to sell. The magistrates fined Hetherington £20 with costs and a cheque was immediately handed in for the amount. This is an important case and probably only one of many likely ere long to come before the magistrates. It demonstrates that the existing law is able to put a stop to some forms of unqualified practice. Unfortunately it is not at present able to altogether prevent unqualified practice, but now that the General Medical Council has prohibited the employment of unqualified assistants by medical men there are good grounds for applying to Parliament to strengthen the law so as to make it possible to put a stop to the practice of medicine and surgery by unqualified men unconnected with qualified practitioners.

The Health of Newcastle-upon-Tyne during the Year 1897.

Dr. H. E. Armstrong, the medical officer of health, has just submitted his annual report for the year 1897. The death-rate has been less than that for the whole of the 33 large towns of the United Kingdom—viz., 18·7 per 1000. There have been fewer deaths from zymotic diseases than in 1896. Dr. Armstrong dwells upon the necessity of the dairies outside the city being regularly inspected, as several cases of enteric fever in the city had been traced to some of them. During the year house accommodation for 1173 families had been provided and 2173 marriages were registered, the highest number on record since 1874. The report is a most satisfactory one.

The Site for the New Infirmary, Newcastle-upon-Tyne.

On April 22nd a public meeting was called by the Mayor of Newcastle for the purpose of confirming the action of the Town Council, which is promoting a Bill before Parliament one item of which is for permission to hand over to the governors of the Royal Infirmary 10 acres of the Leazes upon which to build the new infirmary which Mr. J. Hall has undertaken to erect. The meeting was held in Olympia, which is the largest hall in the city, and was presided over by the Mayor. It was not largely attended and to the general surprise a considerable majority of those present voted against the Bill. A poll was demanded and towards the end of the present month the result will be known. It will be a most unfortunate thing if the property owners and the ratepayers declare against the Bill, and it is believed that there will be an overwhelming majority of votes recorded in favour of the promotion of the Bill. In the meantime meetings of workmen are being held and largely attended at the street corners of the town, where addresses are delivered by town councillors and others in favour of the Bill. Whether it is altogether a wise thing thus to appeal to one section of the community upon an important question affecting the interests of all the inhabitants of Newcastle is a question upon which there is room for more than one opinion. Certainly it tends to introduce a class element into the controversy which it is extremely desirable not to stir up. If by any chance Mr. John Hall's gift of £100,000 should be lost to the sick and lame poor that will be one of the greatest misfortunes possible. The infirmary position is a strong one—the whole of the acting staff have expressed their opinion that the Leazes would be an excellent site, and it is one of those mentioned by Mr. J. Hall in his letter to the committee upon which he would be willing to build. The stewards of the freemen and the corporation are willing to allow the infirmary to be built upon the Leazes. The opposition comes from a section of the freemen, from some property owners residing near the Leazes and from a number of Novocastrians who are unwilling under any circumstances for any part of the town moor to be built upon—for which view there is undoubtedly much to be said. It is announced that should the poll be in favour of building the infirmary on the Leazes the Bill will be opposed in Parliament. It is to be hoped, however, should the poll be in favour of the Bill, the opposition will cease. It would be far better for all concerned that the town should be allowed to manage its own affairs.

Gratuitous Medical Aid in Newcastle-upon-Tyne.

At the weekly meeting of the committee at the Royal Infirmary on May 13th a member stated that 83,000 persons

received relief from the various medical charities in the city during the year 1897—some 40 per cent. of the inhabitants of the town. From the reports of the charities it may appear that 83,000 persons received relief, but it is exceedingly doubtful as to whether this is so. It is more than probable that the same person is entered many times as a patient, and even if 83,000 persons did receive relief it is quite certain many of them were not resident in Newcastle. The idea is prevalent that too many persons are relieved by the medical charities, and the matter having been raised and relegated by the committee to the medical staff of the infirmary to inquire into and report upon, some reliable data are likely to be obtained.

May 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Commissioner of the Local Government Board in Ireland.

SIR FRANCIS MACCABE, the Medical Commissioner of the Local Government Board, has recently retired under the "65" rule after a long and distinguished career in the public service. He filled the position of a medical inspector under the board for many years and was appointed a Royal Commissioner to inquire into the causes of the high death-rate in Dublin in 1879. He has been since then a member of several departmental commissions to investigate matters in connexion with prison dietaries and lunacy administration in Ireland. The ability with which he discharged his difficult duties has never been questioned. The appointment of his successor in office was publicly announced on May 12th, but it had been known for many months that the able and efficient medical inspector for the Dublin district had proved himself to be the only proper successor to Sir Frances Maccabe. The name of Mr. Thomas Stafford as chief medical inspector under the Local Government Board is well known. It is recognised with satisfaction that he as the new medical commissioner will deal with the responsibility as regards the management of the union hospitals and the dispensing medical officers in Ireland under the new board, of which he is now a member, in a large and commonsense fashion and with a keen regard to the requirements of modern science in connexion with sanitation.

Londonderry Lunatic Asylum.

The Privy Council have sanctioned an increase of £50 to the salary of the medical superintendent, Dr. Hetherington.

The Medical Staff of the Tirah Expedition in India.

Amongst the officers specially mentioned in Sir William Lockhart's despatches I find the name of a Belfast man, Surgeon-Major Samuel Ferguson Bigger, M B. Lond. He left his residence, Ardrie, Belfast, in September, 1897, while enjoying a well-earned leave after the Chitral campaign, to take part in the Tirah expedition. Sir William Lockhart writes: "The officers of the Army Medical Staff and of the Indian medical services have fully maintained their high reputation by their attention to the sick and wounded both under fire and in hospital." Dr. Bigger has been gazetted a Surgeon-Lieutenant-Colonel.

The Belfast (Corporation) Hospitals Bill.

Information has reached Belfast that the opposition to this Bill, which comes before a Select Committee of the House of Commons this week, has been withdrawn.

The Proposed New Asylum for County Londonderry.

There can be no doubt that throughout the county of Londonderry there is a widespread opposition amongst the ratepayers to the erection of the new asylum at Londonderry and this on many grounds. It is argued that owing to the poor agricultural prospects it is unfair to increase taxation for the erection of new buildings when many of the unfilled workhouses in different parts of the counties might be utilised for the housing of harmless lunatics; and it is also felt that the new asylum will not be at all central in its position and that the county is not properly represented on the board of governors. The delay in reference to the contracts (as reported in THE LANCET of May 7th, p. 1287) has again drawn attention to the matter, and at the Limavady Board of Guardians on May 16th it was resolved, after a very important discussion, to pass the following motion: "That the building of the new asylum for this (Londonderry) county be postponed in view of the new Local Government Bill becoming law." It was complained by some of the speakers that the Derry people and the Derry boards had not treated the county ratepayers fairly over this matter. It seems that although the ground for the new asylum at Derry has been purchased no contract has as yet been taken for the building. It is thought the Government want pressure brought to bear on them and that they may leave the whole matter of the erection of the new asylum over until the passing of the Local Government Bill, when of course an entirely new aspect will be put on the matter.

The Weather in Ulster.

We are at present experiencing in Ulster exceptionally bad weather. The nights are cold, severe frosts prevailing, while the days are sunless with frequent showers of rain, often accompanied with hail. Not for years have we had such a cheerless May.

Can Poor-law Medical Officers call in Consultants? Important Decision.

A case in which consultants and Poor-law medical officers were very much interested and which was listed for trial before the County-court judge has just been brought to a termination. Some notes on the subject have already appeared in THE LANCET. About three years ago a sealed order was issued by the Local Government Board to the effect that a Poor-law medical officer is at liberty to call in assistance if required with the consent of the guardians if the delay would not be injurious, but if the case proved to be very urgent then the services of "the nearest duly qualified medical practitioner" should be requisitioned. At the instance of Poor-law medical officers the Irish Medical Association wrote to the Local Government Board pointing out that "the nearest duly qualified medical practitioner" may not be in a position to render the required assistance and asking the board to define exactly how the medical officer should act under the circumstances. The Local Government Board declined to give the desired information and in polite language suggested that the subject was not one about which the association need concern itself. Some months ago a man was admitted to the Mitchelstown Workhouse Hospital suffering from depressed fracture of the skull in connexion with which serious symptoms had set in. The master, at the request of Mr. Walsh, the medical officer, telegraphed for Dr. Corby of Cork. Dr. Corby saw the patient in consultation with Mr. Walsh and proposed operation, but the patient persistently declined to permit it. In due course Dr. Corby applied to the guardians for his fee, but they stated that they could not pay it as the terms of the sealed order of the Local Government Board had not been complied with. Dr. Corby wrote to the Local Government Board explaining the circumstances of the case, suggesting that the Board could not have intended that their sealed order should have been interpreted so literally, and asked them to instruct the guardians as to their duties. The Board simply forwarded the letter to the guardians, but on being still further pressed they hinted that if the guardians passed a cheque for the amount of the fee they (the Local Government Board) would probably raise no objection. However, the guardians feared being surcharged by the auditor and persisted in refusing to pay. Dr. Corby accordingly instituted legal proceedings and, knowing the case would have far-reaching effects for the profession, engaged counsel. A defence was entered by the guardians, but there was an unexpected development a few days prior to the commencement of the sessions. The guardians' solicitor wrote to say that acting on the instructions of the Local Government Board auditor he was prepared to consent to a decree for the debt and costs. This action of the Local Government Board is regarded as the prelude to the withdrawal of the objectionable sealed order, especially as the *personnel* of the Local Government Board has been almost completely changed during the past week.

(FROM OUR OWN CORRESPONDENT.)

Immunity of Arabs against Typhoid Fever.

M. VINCENT (Val-de-Grâce) stated at a meeting of the Academy of Medicine held on May 10th that he has found that French soldiers are on an average a hundred times more

subject to typhoid fever than native soldiers, a singular observation, because this disease is in general serious when it attacks Arabs. The comparative exemption of the Arabs depends, in his opinion, neither on a previous attack nor on a slow acclimatisation consequent on residence in towns, but on a natural immunity comparable to the immunity of negroes against yellow fever or of Algerian sheep against anthrax. M. Vincent endeavoured to discover if the blood obtained from Arabs caused agglutination of typhoid bacilli. The blood of 23 natives was used for that purpose, but it presented no distinct serum reaction, the phenomena being exactly the same as those yielded by the blood of persons susceptible of the infection of typhoid fever. This constitutes a new proof that the agglutinating power of blood is not necessarily connected with immunity, whether natural or acquired, and that the serum reaction is a reaction of infection and perhaps of defence, but not a reaction of immunity.

Orthoform in Gynæcology.

At the same meeting of the Academy of Medicine M. Pozzi presented a communication by Dr. Blondel on Various Applications of Orthoform in Gynæcology, especially for the Production of Local Anæsthesia of the Uterus in the Treatment of Endometritis and even in Curetting. Orthoform, the scientific name of which is para-amidometoxybenzoic acid, is a derivative of cocaine and possesses a similar anæsthetic power, which may, however, be prolonged for twenty-four hours and is, moreover, absolutely harmless. Dr. Blondel has employed for uterine dilatation laminaria tents which had been kept for eight days in ether saturated with orthoform and were found to produce in almost all cases only slight pain. A series of 50 patients were successfully treated for endometritis in an average period of three weeks by the employment of intra-uterine drainage with antiseptic gauze soaked with glycerine, a treatment which Dr. Blondel has made use of for six years with good results. Hitherto it has been rather painful, but after the addition of orthoform suspended in the glycerine the patients have felt no pain and have been enabled to go about during the time that they refrained from following their occupations. Curetting could be effectually performed without pain if the uterus was filled with orthoform gauze an hour before the operation.

Statistics of Diphtheria.

At a meeting of the Société Médicale des Hôpitaux held on April 15th M. Sevestre submitted statistics of diphtheria in the Children's Hospital during the year 1897. Among 580 patients the total mortality was 17·4 per cent. If the deaths which occurred during the first twenty-four hours after admission be deducted the mortality falls to 10·8 per cent. Various doses of serum were given, the average amount injected being 20 c.c. There were 341 cases of croup, among which intubation was performed on 202 children. At the same meeting M. Richardière submitted to the society the statistics of diphtheria at the Hôpital Trousseau for the first six and the last two months of the year 1897. It included 696 patients, of whom 125 died, giving a mortality of 17·9 per cent. On deducting 31 cases in which death occurred in less than twenty-four hours after admission the mortality is reduced to 13·5 per cent. Among these patients 344 cases of diphtheria which were not operated on gave a mortality of 4·1 per cent. Intubation was performed on 172 children, of whom 47 died, giving a mortality of 27·2 per cent. The cause of death after operation was almost invariably broncho-pneumonia. Among 11 cases in which primary tracheotomy was resorted to there were 5 deaths, or a mortality of 45·4 per cent. Secondary tracheotomy, after intubation, was performed 55 times; only 11 of these children survived.

The New Director-General of the Assistance Publique.

Dr. Napias, member of the Academy of Medicine, Inspector-General to the Ministry of the Interior, founder and general secretary of the Society of Public Medicine, has just been appointed Director-General of the Assistance Publique at Paris, in succession to Dr. Peyron, who resigned with the intention of devoting himself to politics and offered his services to the electorate of Seine et Oise but has not been successful. Dr. Napias is an eminent authority on all questions of poor relief and hygiene. His sterling qualities, both as a thinker and a man, are recognised on all sides and it will be generally admitted that no better selection could have been made.

A Notorious Murderer.

The notorious Vacher, who was arrested last year after having committed 20 murders according to his own confession and probably more than as many again, has been examined by three medical men familiar with mental disorders, Dr. Lacassagne, Dr. Rebatel, and Dr. Piéret. They divided the scope of the examination into distinct sections. Dr. Piéret took up the part of Vacher's life previously to his manifold crimes, from childhood until joining his regiment. He pointed out the prisoner's hereditary defects, his life in monasteries, his endeavour to murder his sweetheart followed by attempted suicide, and lastly his confinement for a year in a lunatic asylum. Dr. Lacassagne examined the period during which the various crimes were committed, a task which involved the study of more than 200 police records. According to him the prisoner's responsibility is unquestionable, full and complete, and the precautions which he took after each of his crimes to put the police off his track show the professional criminal. Finally, Dr. Rebatel has made a study of the man since his imprisonment, during which he feigned insanity and said that he was a messenger from heaven. The general conclusion of the three experts combined, arrived at after a long and conflicting discussion, was that the prisoner's hereditary defects and his antecedents were such as to warrant the opinion that his responsibility for his actions was in some degree impaired.

Medical Victims to Duty.

Dr. Davaine has just died at the age of twenty-nine years, a victim to duty. Some days ago he was sent for to attend a young child from whom he contracted diphtheria which has proved fatal. M. Gaume, a hospital *externe* at Lyons, has died after a short illness from acute septicæmia, the result of making a post-mortem examination of a case of gangrene.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Seidel Trial.

A SENSATIONAL trial, in which members of the medical profession were especially prominent, took place recently before a law-court at Brunswick. The events which led up to these proceedings happened a considerable time ago. The chief surgeon of the Brunswick General Hospital, Professor Seidel, formerly an assistant to the celebrated Professor von Volkmann, was said by some medical men of the town to have infringed the laws of professional etiquette by attending patients of other practitioners. Professor Seidel having heard of this talk, and being unable to obtain a retractation of the charge, unfortunately committed an act of violence by assaulting the author of these rumours with a whip. On account of this it was proposed that he should be excluded from the medical associations of Brunswick, but before the question came to the vote he committed suicide. It was understood from letters left by him addressed to his family and his friends that the occurrence above mentioned was not the only cause of his death, but that there were other intrigues which had rendered his position insupportable. It had been reported to the Government of Brunswick, which has the control of the hospital, that Professor Seidel had neglected his duties by not visiting the hospital wards regularly, that he had caused the death of a patient by performing a laparotomy when he was suffering from a furuncle on one of his fingers, and that he was not sufficiently careful with respect to antisepsis. These rumours, which originated chiefly with Professor Seidel's assistants, induced the Government to interrogate them officially and to open an inquiry. It was also intimated to Professor Seidel that he was suspended from his functions until the completion of the inquiry, but his death occurred before this intention was carried out. In his last letters Professor Seidel declared that he was driven to commit suicide principally by the behaviour of his assistants, whom he had believed to be his friends, and he implored his family to do everything to vindicate his honour. His brother accordingly applied to the leading surgeons of Germany to ask their opinion on the alleged misdemeanours of the deceased. There was a nearly general opinion that the Government of Brunswick had erred in suspending Professor Seidel before he had had an opportunity of defending himself and that the assistants had behaved improperly in intriguing against their chief. Professor von Bergmann of Berlin wrote a letter in which this opinion was expressed in an especially severe

way and it was published by the brothers in the leading papers of Brunswick, where the whole affair had naturally caused an immense sensation. The Government and the assistants thereupon prosecuted the brothers for libel. The trial lasted for five days and the professors of surgery of the two neighbouring universities—Professor Braun of Göttingen and Professor von Bramann of Halle—attended throughout the whole proceedings as medical experts. A great number of witnesses, old patients, hospital nurses, former assistants, &c., were summoned and gave evidence to the effect that the patients liked Professor Seidel and had never felt themselves neglected by him. As to the non-observance of antiseptic precautions it was stated in evidence that the death of a patient which had been attributed to Professor Seidel's carelessness was caused by perforative peritonitis following appendicitis. Other charges made against Professor Seidel were, in the opinion of the experts, not sustained. The greatest sensation was caused when Professor von Bergmann, although seriously ill, appeared before the court demanding to give evidence. The Public Prosecutor was desirous that he should not be heard, for, being the author of the offending letter, he must eventually be regarded as an accomplice of the defendants; but the court, nevertheless, allowed him to speak. In his evidence Professor von Bergmann declared that if a hospital officer could be suspended on charges like those which were imputed to the late Professor Seidel no surgeon could in future be sure of not becoming the defendant in a prosecution and that nobody would undertake to perform operations. The rules of antisepsis were not so precise as was believed by the assistants. He dealt very severely with the behaviour of the latter, saying that he could not criticise them adequately without committing a new offence. He was glad to say that it was the only instance, so far as he knew, of assistants endeavouring to undermine the position of their chief, to whom they ought rather to feel indebted. The other experts coincided in this opinion. The brothers of Professor Seidel were found "not guilty," a verdict which was received by the audience with great applause. The court in delivering judgment on the sixth day of the trial said that the accusations against the late Professor Seidel had been proved to be unfounded and that the defendants had not acted libellously in contradicting them. The whole press published detailed reports of the proceedings and the action of the Government and the assistants was generally condemned.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Quarantine Regulations at El Tor.

THE old regulations for the landing and examination of pilgrims will be enforced this year with more than usual care. It is intended to examine every man for plague by inspecting his tongue, skin, armpits, and groins, and the travellers will be landed in groups of forty or less. A medical officer will be furnished for every lot of 500 pilgrims and he will be responsible among other things for the disinfection of latrines with lime, for the general hygiene of the camp, and for the cleanliness of the food and water. Three hospitals are provided—one for general diseases; one for diarrhœa, which is an annual accompaniment of the pilgrims; and the third for epidemic or infectious disease. The dead will be submitted to necropsy and bacteriological examination. Those arriving earliest are expected to reach Tor about the middle of May and Dr. Armand Ruffer hopes to be there then himself. Ten disinfecting stoves for treating clothes and bedding are already on the spot and they supply a greater quantity of sterilising power than was ever before present.

Presentation to Mr. Milton.

Last week an evening entertainment was given to Mr. Milton by the native doctors, druggists, and nurses of Kasr-el-Aini Hospital, of which he has been the energetic and creative director for the past fourteen years. Speeches were delivered by five of the hosts in classical Arabic, describing some of the reforms instituted by their guest and master. Mr. Milton, in a feeling reply, spoke in English and in French, adding a few words in German and in Arabic. The articles presented to Mr. Milton on the occasion included a very large gold watch from the hospital officials, a silver service from old students of the hospital, and a china coffee service from the native nurses. The whole idea originated with the Egyptians themselves, the occasion being quite unique in the history of this country and proving a very gratifying token that good English work can be fully appreciated by the natives.

British Wounded in the Soudan.

The first convoy of wounded from the Soudan, consisting of 6 officers and 15 men, left Abadia, near Ginanetti, on May 1st; the second, with 6 officers and 29 men, left on May 2nd; the third, with 40 men, left on May 4th; and the fourth and last, with 30 men, will leave on May 7th. In three days after starting they expect to be at Assouan and they ought all to be in Cairo before May 18th. The British troops will remain in tents and huts at Damali and El Sillem, about 11 miles south of Berber, until a further forward movement be taken, which is not expected until September. The hygiene of the camp is excellent, the general health is good, but the prevailing disease for the moment is dysentery. The Roentgen ray apparatus has now reached Cairo from England and will be ready for the next fight. A sergeant-major of the medical staff is in charge of it and a medical officer who is also an expert with the rays is to arrive here shortly.

Cairo, May 4th.

Obituary.

ALFRED JOHN WALL, M.D. LOND., F.R.C.S. ENG.,

INDIAN MEDICAL SERVICE (RETIRED LIST).

ALFRED JOHN WALL was born in 1847, his father being a medical practitioner with a large practice in the West-end of London. He was educated at Epsom College, where he distinguished himself and received from Dr. Thornton, then head master, a very high unsolicited testimonial to his conduct and abilities when he left the College. In 1865 he entered at St. Mary's Hospital, where he was known as a hard worker, and took various prizes. In 1868 he obtained the scholarship for Anatomy there, which carried with it the title and duties of Assistant Demonstrator of Anatomy for the winter session. In 1870 he was appointed resident medical officer to St. Mary's Hospital, and in 1871 he became resident obstetric officer. In 1872 he became a Fellow of the Royal College of Surgeons of England and in 1873 he went up for the Indian Medical Service competitive examination when he took a high place. In the autumn of the same year he took the degree of M.D. at the University of London. In January, 1874, he went out to India and was almost immediately appointed resident medical officer at Bhangulpore. The following year, when the Snake Poison Commission was instituted, as there was at that time only one other man with his qualifications in the service, although he was so newly entered, he was offered a seat on it. This he accepted and the greater part of the practical work of the Commission fell upon him as the youngest member. He held the post for three years and then as his health was failing he sent in his resignation. He was twice asked to reconsider the matter, but upon adhering to this determination he received a letter of thanks from Government for the valuable work he had done and was offered his choice between the appointment as residency medical officer in Nepaul and deputy professor of anatomy in Calcutta. Considerations of health made him choose the former. Some time afterwards when travelling on furlough he contracted malarial fever, which became complicated with pneumonia and in consequence he came home invalided and never recovered sufficiently to return to India. In 1883 he published a book entitled, "Indian Snake Poisons." He next took up the subject of cholera and followed successive outbreaks of that disease over Europe. In Italy and Sicily he was especially distinguished for his services and the municipal council of one town presented him with an address and the freedom of the place in recognition. The poorer people, too, who shunned their own doctors, thinking that the epidemic had been wilfully produced by them, would rush out of their houses as Dr. Wall passed by and beseech him to go in and help them. In 1893, as a result of these travels and investigations,

he published a book on "Asiatic Cholera," which was favourably reviewed and received.

He had always been an indefatigable student of pathology and he now turned his attention still more closely to it, working at it for many months together in Buda-Pest, Berlin, and Paris. In the former place he did practical work in the laboratory of his friend Dr. Nékám; in the latter he also took the course in bacteriology in the Pasteur Institute. In December, 1897, he left England with the intention of going to the Riviera, there to put into form his pathological notes. But whilst staying in Paris *en route* he became so ill that he was advised to return to England in February, instead of continuing his journey, and went to Hastings. At length his condition became so much more serious that on April 21st he was brought up to London, but he gradually got worse and died on May 2nd, 1898.

A St. Mary's Hospital man and intimate friend of Dr. Wall from student days says of him: "In manner he was diffident, quiet, and retiring. He was extremely well informed in every subject of art, science, and literature—the best possible of companions. He talked German, French, and Italian fluently and was keenly interested in the politics, as well as the literature, of the countries in which he made his temporary home."

ANGUS MACKINTOSH, M.D., L.F.P.S. GLASG.

AFTER an illness of very brief duration Dr. Angus Mackintosh, medical officer of health of the Chesterfield Rural Sanitary District, died at his residence, Gladstone-road, Chesterfield, on May 7th, at the age of sixty-four years. Dr. Mackintosh was a native of Fincastle, Perthshire, and owed his fine physique and imposing personality as well as his love of rural sports to the healthiness of the climate in the charming vale of Athole. He received his medical education at the University of Glasgow, where he carried off from year to year many prizes earning as well the approbation of his teachers and the goodwill of his fellow students. He spent eight years of his professional life in the work of general practice at Callington, Cornwall, but the bent of his mind lay in the direction of his favourite science, preventive medicine, to the literature of which he was a voluminous contributor. He was appointed twenty-five years ago the first medical officer of health of the Chesterfield Combined Sanitary District and continued to discharge the duties of that important post until the day of his death. His successive annual reports, which were often favourably commented on in the columns of THE LANCET show a vast amount of useful sanitary work carried out during his tenure of office towards the sanitary amelioration of this populous district. They were admirable examples of keen observation, close argument, and beautiful diction and will be long remembered by those who read them since they were the outcome of painstaking investigation and original thought. He put his whole soul, mind, and strength into his work and always took his stand rather on the firm ground of fact than on the less certain basis of theory. He loved to examine the foundations on which opinions rest and held fast to the view that correctness of judgment and accuracy of thought are infinitely more valuable than all the speculative knowledge which we can obtain.

Possessed of a dignified presence, an authoritative bearing, and in a pre-eminent degree of the judicial temper, the sanitary authority have lost in Dr. Mackintosh an able officer in whom they reposed every confidence. By many of his colleagues in the public health service, by the members of the medical profession within his district, and by the public whose health he safeguarded for a quarter of a century he will be deeply regretted. The funeral took place on May 10th in the presence of a large assembly of friends, medical men from all parts of the county, and officials of the various public bodies with which Dr. Mackintosh was connected.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ludwig Schillbach, Extraordinary Professor of Surgery in the University of Jena, at the age of seventy-three years.—Dr. Humbert Molière, Physician to the Lyons Hospitals.—Dr. Philogonio Lopes Utinguassu, Assistant Professor of Physiology and Pathological Anatomy in the Medical School of Rio de Janeiro.—Dr. Amedeo Marianelli, Extraordinary Professor of Dermatology and Syphilography in the Medical School of Modena.—Dr. A. Krasovski, formerly Professor of Midwifery and Gynæcology in the Military School of St. Petersburg and Corresponding Member of the Paris Academy of Medicine.

CONGRESS OF INTERNAL MEDICINE AT WIESBADEN.

(FROM OUR BERLIN CORRESPONDENT.)

THE Congress of Internal Medicine was opened at Wiesbaden on April 13th and concluded its work on April 16th. The President was Dr. Schmidt of Frankfort, who in his inaugural address said that the question of medical education which had been chosen as the first subject of discussion was one of great interest because the constant sub-division of medicine and surgery into a number of special branches had made it almost impossible to take a general survey of the whole field of medical knowledge. Nowadays a medical man must be satisfied with keeping himself *au courant* in his speciality and there is no ground for expecting that in the forthcoming century a great genius will arise capable of recombining the disjoined parts of medical science. But even though such an exceptional individual should not be forthcoming, is there any reason for despairing of the future of medicine? This question would not be answered in the affirmative by anyone who had attentively considered the present position of medicine as an art and a science, especially the manner in which laboratory investigations had contributed to the development of methods of treatment. The inquiries necessary for original research had aroused a certain amount of opposition, and as the antivivisectionists are supported in their agitation by women who are fond of dogs and cats so in like manner the medical men ought to look for allies among the mothers whose children owe their recovery from diphtheria to the use of antitoxic serum and among the thousands of patients who have experienced in their own persons the benefits of antiseptics. All these and other improvements were only made possible by experiments on animals. The work of the Congress then commenced with a discussion on

Medical Education.

Professor VON ZIEMSSEN (Munich), who spoke first on this subject, made the following recommendations: The practical and technical education of young medical men should be improved; the duration of the curriculum should be increased; in addition to the lectures on general and special pathology and therapeutics there should be practical courses on the methods of diagnosis (microscopical, chemical, bacteriological, laryngological), on the methods of general therapeutics (dietetic, hydropathic, electric, balneological, &c.), and on the technique of treatment in the hospital wards; the faculties should provide the necessary stock of microscopes, models, and other appliances requisite for clinical study; and the out-patient departments should be made more use of for the purpose of instruction. A "practical year" in a hospital, as proposed in connexion with the contemplated reform of medical examinations and described in THE LANCET of Jan. 4th, 1896, page 74, is very desirable, but this should only be undertaken after the qualifying examinations have been passed.

Dr. VON JAKSCH (Prague) was of opinion that reform in medical education is quite compatible with the existing system of university teaching and that it is not necessary to detach the medical faculties and to institute special medical schools, as has been proposed by some radical reformers. Students ought to be required to attend the medical clinic ten hours every week for two years. Instruction of medical students in hygiene, mental diseases, dermatology, diseases of children, otology and laryngology, dietetic and mechanical treatment and hydro-therapeutics is quite indispensable. An augmentation of the *personnel* and the *matériel* of the clinics will be necessary in order that they may be able to meet the increased demands on them. Specialists ought to have to pass special examinations.

In the course of the discussion Professor JÜRGENSEN of Tübingen pointed out that the importance of internal medicine was not fully recognised by young medical men who were dazzled by the great successes of surgery, but in actual practice nine-tenths of the cases they had to treat were medical.

The utility of the practical year was denied by Professor QUINCKE of Kiel and Professor HOFMANN of Leipsic who were of opinion that it might be replaced by more extended instruction in the out-patients' departments.

The Therapeutic Use of Hot Dry Air.

Dr. MENDELSSOHN (Berlin) said that the treatment of chronic arthritis was almost exclusively a question of temperature and that the most efficacious method was the application of hot dry air, which allows a high temperature to be maintained for as long a time as may be required and does not produce any undesirable symptoms. Dr. Mendelssohn following the example of English physicians has made use of hot dry air and has proved that temperatures of from 120° to 140° C. (from 248° to 284° F.) could be borne by patients for several hours. The subjective sensations were not disagreeable and no unfavourable consequences were produced on either the pulse or the temperature. The immediate local effect on the joints was at once very obvious, especially in chronic rheumatism, gout, and other affections of the joints; sometimes after the first application of the hot air they became temporarily more moveable, but, of course, to obtain a substantial improvement the treatment must be applied for a longer time.

Treatment of Chlorosis by Hot Baths.

Dr. ROSIN (Berlin) said that articles published by Professor Baeltz of Tokio, Japan, had induced him to treat a number of chlorotic patients by baths at 40° C. (104° F.). According to Professor Baeltz the Japanese habitually bathe, not in cold water, but in water at 45° C. (113° F.). They are said to feel quite comfortable after these very hot baths and not to be liable to catch cold. These statements have been tested by experiments made in the medical clinic of Halle, and Dr. Rosin has found that the muscular pain of which chlorotic patients so often make complaint is very soon relieved by this mode of treatment. The baths are given three times a week just before bedtime. On the first occasion the patients remain in the baths for a quarter of an hour and afterwards for half an hour, during which time they perspire abundantly, and are subsequently douched and rubbed. More than three baths a week are unnecessary and the whole course of treatment lasts four weeks. After the baths a sensation of general comfort is experienced, the appearance and the appetite improve, and the muscular pains disappear. These hot baths produce an effect similar to that of the expensive carbonic acid and chalybeate mud baths and are, of course, more within the reach of people of moderate means. Dr. Rosin expressed the opinion that some forms of constitutional disease may be more advantageously treated by inducing perspiration than by internal medication.

Treatment of Diabetes.

Professor LEO (Bonn) introduced the subject with an account of experiments made on dogs for the purpose of investigating the origin of diabetes. He concluded from them that the presence of sugar in persons who are addicted to beer drinking was caused by a toxic product of the yeast cells. Persons in whose family diabetes is hereditary ought, therefore, to avoid the use of beer and those who are already diabetic ought, of course, to do likewise. In order to reduce the formation of sugar in the organism carbohydrates ought to be taken by the patients as sparingly as possible; in fact, they ought at the beginning of the treatment to be absolutely excluded from the dietary, but not for longer than from three to five weeks, during which time the food should principally consist of albumin, fat, and vegetables with nothing but tea or coffee to drink. After this time amylaceous food may be taken in very limited quantities. In somewhat severe cases a period of abstinence is necessary three times a year. Massage is useful for increasing metabolism and strengthening the muscles. Opium may be mentioned as an internal remedy which is efficacious in some instances. A new yeast product, termed zymase, had an obviously good effect in one case, but the observations were not yet finished. The mineral waters of Karlsbad, Neuenahr, &c., were sometimes very valuable, although they had no specific action against the disease.

Dr. GRUBE (Neuenahr) discussed the conditions which presented themselves when diabetes was complicated with albuminuria. Among 473 cases of diabetes examined albumin was found to be present in 191. There are five forms of diabetic albuminuria: (1) the albuminuria of the final stage of far advanced diabetes; (2) that produced by cardiac failure; (3) that due to senile alterations of the blood-vessels, which usually appears earlier in diabetics than in other persons; (4) functional albuminuria which may be caused by irritation of the kidneys by the sugar excretion; and (5) the albuminuria of chronic nephritis.

Chronic Diseases of the Heart.

Dr. SCHOTT (Nauheim), speaking on this subject, said that myocarditis is much more frequent than is generally believed; it is caused by arterio-sclerosis, syphilis, or febrile diseases. Fatty degeneration of the cardiac muscle is still more frequent, the muscular substance being affected by over-exertion of the mental or bodily powers and by abuse of tobacco and alcohol. The principal causes of cardiac trouble are advanced life, the climacteric period in women, and excesses of various kinds, especially masturbation during adolescence. Treatment must first aim at increasing the efficiency of the heart muscle. Digitalis still continues to be regarded as the standard remedy for internal administration. Oertel's "terrain cure" and Zander's gymnastic method also give good results. His (Dr. Schott's) own mechanical method has the advantage of being easily practised and of allowing exact graduation. Its contra-indications are aneurysm of the heart and the great vessels and advanced arterio-sclerosis especially where apoplexy is imminent. Dr. Schott showed a great number of skiagraphs by which it was proved that mechanical treatment caused stronger contraction of the heart and consequently a diminution in the size. On the other hand, in a case of advanced arterio-sclerosis and aneurysm of the aorta the heart was proved to have become still more dilated.

Arthritis Deformans.

Dr. BADT (Salzschlirf) drew attention to the frequency of this disease in women especially at the climacteric period. Of 53 cases observed by him 6 per cent. were men and 94 per cent. were women; in 80 per cent. of the latter the illness began at the age of from forty to fifty years. Dr. Badt was therefore of opinion that the administration of oophorin, which has proved useful in climacteric troubles, might be a valuable adjunct to other therapeutic measures such as baths, massage, &c.

The Urine in Pneumonia.

Dr. FRIEDEL PICK (Prague) stated that he had observed that the urine, which is strongly acid during the feverish stage of pneumonia, at once becomes neutral or alkaline after the crisis. This symptom, which lasts for about twenty-four hours and sometimes even for thirty-six hours, may be caused by the absorption of the sodium compounds contained in the pneumonic exudation. The normal reaction usually reappears after an interval of twenty-four hours.

Intestinal Auto-intoxication.

Dr. MÜLLER (Marburg) said that the term auto-intoxication denoted certain symptoms due to toxic products of metabolism in the individual affected. According to Bouchard's views uræmia, eclampsia, diabetic urine, gout, and the symptoms caused by diseases of the thyroid and the suprarenal glands are auto-intoxications, but intestinal auto-intoxications do not belong to this category as they are produced by saprophytes in the gastro-intestinal canal. Some alleged auto-intoxications must be regarded as cases of poisoning due to unwholesome food. The definite putrefaction products elaborated in the intestines—such as indol, phenol, and skatol—are only very slightly toxic, but there is no doubt that the contents of the intestines may pass into a state of toxic decomposition as is proved by the serious symptoms which may occur in some gastric and intestinal diseases, especially in children. The most favourable condition for such auto-infection is the obstruction to the progress of the fæces which is present in peritonitis and ileus. Dr. Müller said that in classifying an illness as an auto-intoxication it is necessary to be able to define the special toxin in each individual case, but this is as yet far from being accomplished, for the doctrine of auto-intoxication is founded on only a very few exact facts. With respect to treatment, it has been stated that destruction of the bacteria in the intestines is not possible. The effect of calomel does not depend on its antiseptic but on its purgative action.

Professor BRIEGER (Berlin) remarked that the theory of auto-intoxications is founded on the presence of toxins in the urine and the perspiration, but hitherto it has only been possible to isolate those toxins in a few instances. Brieger and Wassermann have succeeded in obtaining a toxalbumin from the urine of patients with erysipelas, whilst Roos

found a similar toxalbumin together with putrescin and cadaverin in the urine of patients with gastro-enteritis. Toxalbumin is present also in the urine of dyspeptic infants. The toxic products of the perspiration are very uncertain. With regard to treatment Professor Brieger recommended diaphoretic and purgative medicines together with washing out the stomach and rectum.

Iodothyrin.

Professor ROOS (Freiburg) stated that the iodothyrin obtained from the thyroid glands of sheep is an albuminous substance containing about 4 per cent. of iodine. Thyroid glands in a state of advanced colloid degeneration, although they contained much iodine, nevertheless yielded only very little iodothyrin. From this Professor Roos inferred that in these diseased glands only a relatively small portion of the iodine was contained in the substance corresponding to iodothyrin and he suggests that in goitre there is an abnormal distribution of iodine in the thyroid gland.

Intradural Injections.

Dr. JACOB (Berlin) said that puncture of the spinal canal, introduced by Professor Quincke in 1891, had been valuable for diagnostic purposes but that its therapeutic utility was less apparent. In particular the diminution of the cerebral pressure brought about by puncture had not been attended by any obvious benefit. Dr. Jacob has made experiments in animals for the purpose of investigating the effects of increase of pressure. He injected into the subarachnoid space of dogs about 70 c.c. of a 0·1 per cent. solution of common salt coloured with methylene blue and this fluid was found at the necropsy to have passed through the whole cerebro-spinal canal and made its way into the brain. But notwithstanding the immense increase of pressure in the cerebro-spinal fluid owing to the injections no symptoms of cerebral pressure showed themselves. Puncture of the cerebro-spinal canal is therefore useless as a means of treatment, for the symptoms of cerebral pressure are not dependent on the increase of fluid in the canal. In a second series of experiments Dr. Jacob made injections into the subarachnoid space for therapeutic purposes. In cases of meningitis the subarachnoid space was washed out with 0·1 per cent. solution of common salt or with carbolic acid solutions varying in strength from 0·5 to 1 per cent. An injection of 25 c.c. of a 4 per cent. solution of potassium iodide in dogs caused dangerous symptoms of poisoning, which, however, soon disappeared. This substance must therefore be employed in weak solutions.

Papers were also read by Dr. Engel (Berlin) on the Blood Cells in Pernicious Anæmia, by Dr. Bornstein on Saccharin, by Dr. Magnus-Levy on the Alkalinity of the Blood in Gout, by Dr. Edinger (Frankfort) on a Disease Resembling Tabes, by Professor Petruschky (Dantzig) on Streptotrichosis, by Professor Wyss (Zürich) on Acute Hæmorrhagic Myelitis, and by Dr. Pässler (Leipsic) on the Treatment of Disorders of the Circulation in Infectious Diseases. The next Congress will meet at Carlsbad.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination for the diploma of Fellow at a meeting of the Board of Examiners:—

Monday, May 16th:

Charles Henry Bullen, Mason University College, Birmingham; William Gough, B.Sc. Lond., Yorkshire College, Leeds; John Ikin Sangster, M.B., Ch.B. Adel., M.R.C.S. Eng., L.R.C.P. Lond., Adelaide University, Yorkshire College, Leeds, and London Hospital; Evelyn Davison Telford, Cambridge University; Albert Ernest Finney and William Paynter Noall, Owens College, Manchester; William Stewart Dickie, St. Mungo's College, Glasgow; and William John Young, University College, Liverpool.

Eight gentlemen were referred for six months.

Tuesday, May 17th:

Nathaniel Bishop Harman, M.R.C.S. Eng., L.R.C.P. Lond., B.A., M.B., B C. Cantab., Cambridge University and Middlesex Hospital; John Thomas Hewetson, M.R.C.S. Eng., L.R.C.P. Lond., M.B., C.M. Edin., Edinburgh University and King's College Hospital; Arthur Gentry Pitts, Charing-cross Hospital; Norman Frederic Ticehurst, B.A. Cantab., Cambridge University and Guy's Hospital; and Arthur Solomon Morley, St. George's Hospital.

Eleven gentlemen were referred for six months.

The following are the arrangements for the forthcoming final examination for the Fellowship, for which 40 gentlemen have entered their names.

Monday, May 23rd, Written Examination, 1.30 P.M. to 5.30 P.M., at Examination Hall; Tuesday, May 24th, Clincal Examination (written and *vivâ voce*), 2.30 P.M. to 5.30 P.M., at Examination Hall; Wednesday, May 25th, Operations, 1.30 P.M. to about 6 P.M., at Examination Hall; Thursday, May 26th, Surgical Anatomy, 2 P.M. to 4 P.M., at Examination Hall; Friday, May 28th, Pathology, 5 P.M. to 7.40 P.M., at Royal College of Surgeons; Saturday, May 28th, Pathology, 3 P.M. to 5.40 P.M., at Royal College of Surgeons. Candidates will be required to attend on May 23rd, 24th, 25th, and 26th, and on the 27th or 28th.

UNIVERSITY OF CAMBRIDGE.—At a congregation on May 12th the following medical and surgical degrees were conferred:—

Doctor of Medicine.—Tice Fisher Budden, Caius; Hugh Edward Wingfield, Caius; George Porter Mathew, Trinity Hall; and Harry Hollis, Sidney Sussex.

Bachelor of Medicine and of Surgery.—Francis Raynes Martin, Caius; and Charles Albert Trouncer, Jesus.

Bachelor of Surgery.—Henry Ernest May, Clare.

At the third examination for medical and surgical degrees, Easter Term, the following candidates passed in the subjects indicated:—

Part I. Surgery and Midwifery.—Barnes, B.A., Christ's; Boulton, B.A., Clare; Byles, King's; W. D. Chapman, B.A., Corpus Christi; H. N. Clarke, B.A., Trinity; Denyer, M.A., Queen's; Dore, B.A., and W. Eardley, M.A., St. John's; Fryer, B.A., Christ's; Garrood, B.A., St. John's; Glasier, B.A., Emmanuel; Glynn, B.A., Clare; W. D. Harmer, B.A., King's; Hart-Smith, B.A., and Hay, B.A., Gonville and Caius; Jordan, B.A., Sidney Sussex; Kemp, B.A., Clare; Letchworth, B.A., Emmanuel; A. F. McCallan, B.A., Christ's; H. F. Parker, B.A., Emmanuel; Pettinger, B.A., H. Selwyn; S. P. Pollard, B.A., Gonville and Caius; Powell, B.A., Emmanuel; S. B. Reid, M.A., St. John's; R. E. Sedgwick, B.A., Gonville and Caius; Sewell, B.A., Pembroke; C. C. Simson, M.A., and G. R. Slade, B.A., Trinity; Stacey, B.A., and F. W. Sumner, B.A., St. John's; Sutcliffe, B.A., Emmanuel; Talbot, B.A., King's; Tallent, B.A., and E. C. Taylor, B.A., St. John's; Thorp, B.A., Emmanuel; I. Ll. Tuckett, M.A., Trinity; Ware, B.A., Pembroke; W. K. Wills, B.A., St. John's; R. J. Wilson, B.A., Emmanuel; and A. G. Wilson, B.A., Gonville and Caius.

Part II.—Betteridge, B.A., Gonville and Caius; T. H. Brown, B.A., Pembroke; Byles, King's; Carter, B.A., Jesus; Corner, B.A., Sidney Sussex; H. G. Deller, B.A., Trinity; A. B. Green, M.A., Downing; Gregory, B.A., St. John's; Harrison, B.A., Magdalene; Heilborn, B.A., Gonville and Caius; Levick, B.A., Jesus; E. A. C. Matthews, B.A., Trinity; H. E. May, M.A., and F. A. Mills, B.A., Clare; Naish, B.A., Trinity; Prest, B.A., St. John's; Ransome, B.A., Gonville and Caius; Roderick, B.A., Emmanuel; J. E. Sandilands, B.A., Trinity; Sargent, B.A., St. John's; Hon. G. H. Scott, B.A., Trinity; and C. White, B.A., Christ's.

ROYAL COLLEGE OF SURGEONS IN IRELAND: DENTAL EXAMINATION.—The following candidates having passed the necessary examination have been admitted Licentiates in Dental Surgery of the College:—

J. J. Hayden, Dublin; F. H. G. Pakenham, Dublin; T. J. Rea, Belfast; and A. G. Taylor, Glasgow.

The following candidates passed the primary part of the examination:—

Miss H. A. Hall, Manchester; and J. I. Potter, Kilkenny.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—The following candidates having passed the examination for the Licence in Midwifery of the Royal College of Physicians of Ireland were admitted as Licentiates on Friday, May 13th:—

G. H. Brand, L.S.A., and A. W. Shea, L.S.A.

FOREIGN UNIVERSITY INTELLIGENCE. — *Basle:* Dr. E. Kaufmann of Breslau has been appointed to the chair of Pathological Anatomy, vacated by the resignation of Professor M. Roth.—*Constantinople:* Dr. Düring, Professor of Dermatology, has been appointed Sub-director of the Haidar Pasha Hospital and has been granted the rank of Pasha.—*Cracow:* Dr. Ladislas Reiss has been promoted to an extraordinary Professorship of Syphiligraphy. Dr. Rudolf Trzebicky has been appointed Extraordinary Professor of Surgery.—*Iurieff:* Dr. N. de Savelieff of Moscow has been appointed Extraordinary Professor of Propædeutics and Medical Pathology—*Padua:* Dr. V. T. Tettenero has been recognised as *privat-docent* of Midwifery and Gynæcology. Dr. Bertelli of Pisa has been recognised as *privat-docent* of Anatomy.—*Philadelphia (Jefferson Medical College):* Dr. Edward P. Davis has been appointed Professor of Midwifery and Dr. E. E. Montgomery Professor of Gynæcology.—*Prague (German University):* Dr. Alfred Fischel has been recognised as *privat-docent* of Anatomy and Embryology. (*Bohemian University*): Dr. Em. Formanek has been recognised as *privat-docent* in Medical Chemistry.—

Rome: Dr. Agenore Zeri has been recognised as *privat-docent* of Medical Pathology.—*St. Petersburg (Military Medical Academy):* Dr. Demetrius Kosorotoff of the Legal Faculty of the University of St. Petersburg has been appointed Extraordinary Professor of Forensic Medicine and Toxicology. Dr. Kedrovski has been recognised as *privat-docent* of Medical Bacteriology.—*Turin:* Dr. Lorenzo Scofone has been recognised as *privat-docent* of Materia Medica and Experimental Pharmacology.—*Vienna:* Dr. Neuburger has been recognised as *privat-docent* of the History of Medicine.

WHITSUNTIDE ON THE CONTINENT. — Cheap tickets available for eight days will be issued to Brussels during the week ending May 28th *viâ* Harwich and Antwerp by the Great Eastern Railway Company. Passengers leaving London in the evening reach Brussels next morning after a comfortable night's rest on board the steamer. For visiting The Hague, Amsterdam and other parts of Holland, the Rhine, North and South Germany, and Basle for Switzerland special facilities are offered *viâ* the Great Eastern Railway Company's Royal Mail Harwich-Hook of Holland route, through carriages being run to Amsterdam and Berlin; through carriages with restaurant cars are also run to Cologne and Basle. The General Steam Navigation Company's fast passenger steamers will leave Harwich on May 25th and 28th for Hamburg, returning May 29th and June 1st.

DIPHTHERIA IN LONDON.—The deaths registered from diphtheria in London last week only amounted to 20, an abnormally low figure as compared with 31, 39, and 27 in the preceding three weeks. Not only, however, was the total of last week below the number of deaths registered from the disease in London during many months past, but it was as much as 17 under the corrected decennial average for the corresponding week of the period 1888-97. Three deaths were those of persons belonging to the Poplar sanitary area. All the deaths were of persons under twenty years of age, though only two were of infants. The admissions to hospital showed no falling off, being 131, against 105, 110, and 133 in earlier weeks, whilst there remained 949 patients under isolation for diphtheria on Saturday last, as compared with 942 on the Saturday preceding, and 930 on the last day of April. The deaths registered from the disease in the Outer Ring also showed a diminution, 10 being the total, of which 3 occurred in Edmonton and 3 in West Ham registration districts.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—A meeting of this society was held on April 29th, Dr. Dundas Grant, President, being in the chair. Dr. Barclay Baron (Bristol) showed a case of Cyst of the Epiglottis in a middle-aged man. There were practically no symptoms, merely a tendency to "hawking" which was probably due to elongation of the uvula. On the lingual surface of the epiglottis there were two cysts, one about ½ in. across, covered with thick mucous membrane, with dilated vessels on its surface and another of about the size of a pea.—Mr. Wyatt Wingrave showed a woman, aged sixty-six years, from whose right vocal cord a fibroma had been removed six months previously with a Krause's snare. There had been no return. He also showed a similar case in a man, aged thirty-eight years, where a fibroma had been partially removed from the right vocal cord by Dr. Dundas Grant's laryngeal cutting forceps. The structure was an angio-fibroma and recurrence was taking place.—Dr. Brown Kelly (Glasgow) read a paper on Cysts of the Floor of the Nose. He described 3 cases of his own and referred to 9 others which have been recorded. In all of these the cyst appeared at the anterior end of the floor immediately behind the junction of the skin and mucous membrane. He had found large ducts in this region, which indicated the probable origin. The most marked sign was prominence of the ala nasi of the affected side. The cyst might be treated from the nose, but when large it should be dissected out from the gingivo-labial fold.—Mr. Wyatt Wingrave read the notes of 3 cases of Lupus of the Nose in which the new tuberculin had been employed by Mr. Lennox Browne and himself. The results did not appear to be encouraging.—The President cited a case of Lupus of the Cheek shown by Dr. Heron at the Clinical Society, where healing had resulted from the injection of new tuberculin.—Mr. Stoker showed a case of Rodent Ulcer of the Nose and a case of Lupus of the Face treated by concentrated sun's rays applied by means of a bi-convex glass lens of 4 in. focus. The results of a series of observations as to the penetrating effect of sun's rays on raw meat had led him to adopt this treatment, which so far had realised his hopes.—The President brought forward several cases of Chronic Dry Catarrh of the Middle Ear of the Sclerotic Type. These had resisted the usual methods of treatment and he had tried the effect of mechanical vibration applied to the dorsal spine. Under this "indirect massage" of the tympanitic structures (presumably of the stapedio-vestibular articulation) considerable improvement had taken place, as was shown by several of the cases presented.

THE LATE DR. HAMILTON KINGLAKE. — Dr. Hamilton Kinglake of Taunton, who died there on May 7th, was a son of the late Mr. William Kinglake of Taunton and the last surviving brother of the late Mr. Alexander William Kinglake, the historian of the Crimean War. Dr. Kinglake graduated as M.D. at Edinburgh University in 1837.

A DAY OF REST IN THE COUNTRY FOR THE METROPOLITAN NURSES.—On Friday, June 3rd next, an opportunity will be offered to the nurses of the metropolitan hospitals and nursing institutions to enjoy a day in the country at Hertingfordbury. Three short services will be given in the parish church with addresses by the Bishop of Thetford. The expense to those attending will not exceed 2*s.* 6*d*, inclusive of the journey from town. Those who may desire to be present should communicate as soon as convenient with the Rev. A. B. Locke, St. George's Hospital, S.W., or with the Rev. Canon Burnside, Rector, Hertingfordbury, Hertford.

CORPORATE AND MEDICAL REFORM COMMITTEE.—A meeting of the executive committee was held on May 14th, Dr. T. Granville Hockridge being in the chair. A letter was read from Dr. D. C. McVail (Crown Representative of Scotland on the General Medical Council), acknowledging the letter adopted at the previous meeting of this committee, thanking Dr. McVail for his action in opposition to the principle of registering and recognising midwives at the recent special meeting of the General Medical Council. On the memorial addressed by the committee to the Home Secretary opposing the registration of midwives a statement of the danger and impolicy of such registration prepared by Mr. R. B. Anderson to accompany the memorial, with a prefatory note by a select committee consisting of the chairman (Dr. T. Granville Hockridge), Dr. Boyd Joll, and Dr. Tom R. Taylor, was approved and adopted. The statement included a statement of the case for the registration of midwives communicated by Mr. F. Rowland Humphreys, honorary secretary of the Midwives Bill Committee, with comments thereon. Mr. Anderson stated that he was making arrangements for the publication of the memorial, prefatory note, and statements. On consideration of the fourth report of Mr. Victor Horsley to the registered practitioners of England and Wales the following resolution was unanimously adopted: "That the President be requested to convey to Mr. Victor Horsley, F.R.S., the thanks of this committee for his fourth report to them and other members of his constituency." Certain resolutions were also directed to be sent to Mr. Horsley. The letter of the chairman and honorary secretaries to the Council of the Royal College of Surgeons of England covering copy of Protest and Claim of Right of Members and Fellows to elect the Representative of the College on the General Medical Council was approved and adopted. (It was forwarded last week.) The following reply has been received:—

Royal College of Surgeons of England,
13th day of May, 1898.

GENTLEMEN,—I am directed to inform you that your letter of the 7th inst. and accompanying statement of Protest and Claim have been laid before the Council of the College.

I am, Gentlemen, your obedient servant,
SIBERT COWELL, Assistant Secretary.

T. Granville Hockridge, Esq.
Tom R. Taylor, Esq.
R. B. Anderson, Esq.

A resolution was unanimously adopted inviting Mr. George Jackson to permit himself to be nominated as a candidate for the approaching election to the College Council in support of the policy of the committee and therewith the following resolution was adopted:—

That in order to promote the best interests of the body corporate the Royal College of Surgeons of England, by advancing the right of Fellows and of Members to elect the Representative of the College on the General Medical Council and the claim of the Members to representation on the Council of the College in accordance with the vote of the meeting of Fellows in January, 1896, the President is requested to convey to Mr. Horsley this resolution of this sub-committee by way of

invitation to permit himself to be nominated for election to the College Council at the ensuing elections thereto and to coöperate in inviting the support of the Association of Fellows of the College in these several respects in accordance with its past policy and as the best mode of access to the body of Fellows.

MEDICAL MAGISTRATE.—The Lord Chancellor has appointed Mr. Walter A. Satchell, F.R.C.P. Edin., M.R.C.S., of Ealing, a justice of the peace for the county of Middlesex.

THE LATE MR. EMIL ARNOLD PRAEGER.—Mr. Praeger, whose death is announced as having taken place at Los Angeles, California, U.S.A., on March 6th, had been in practice in that city for about four years, during which time he had become so popular with his medical brethren that he was this year unanimously chosen president of the county medical society. He was a native of England and held the qualifications of L.F.P.S. Glasg. and L.S.A., both of which he took in 1883, afterwards spending a short time in Africa and also practising in England. Some twelve or fourteen years ago he commenced practice in British Columbia and became surgeon to the Vancouver Mining Company there, but on account of the illness of a daughter he sacrificed this position and went to Los Angeles. The *Southern Californian Practitioner* contains a very sympathetic notice of his life and last illness and adds that "he held various important offices in the society, was a regular attendant at all medical meetings, was elected a member of the Faculty of the Medical College, and last year the *Practitioner* was fortunate in securing him for its editorial staff." Mr. Praeger was forty-three years of age. He has left a widow and three children.

QUEEN'S COLLEGE, BELFAST: SESSION 1897-98.—At the class examinations in the Faculty of Medicine recently held in the above College the following prizes were awarded:—Zoology—Senior Division: Frederick Wm. Stewart. Junior Division: Robert James Bethune, Sydney Herbert George Blakeley, Henry Mulrea Johnston, and Thomas Carnwath and James Kennedy Small (equal). Chemistry—Senior: Andrew Adams Rutherford. Junior: James Kennedy Small and Henry Mulrea Johnston. Practical Chemistry—Senior: Thomas Bernard Vinycomb. Junior: Hugh Beaumont Smith and Wm. John Brereton Fergus. Systematic Anatomy—Senior: John Elder M'Ilwaine, John Campbell Rankin, and Hugh Barkley Steen. Junior: David M'Mordie, Albert Lytle Black, and Samuel Robert Hunter. Practical Anatomy—Senior: John Elder M'Ilwaine and John Hope Reford, B.A. (equal), and Thomas Stratford Logan. Second Year: Archibald George Heron and David M'Mordie (equal). First Year: Robert Alexander Stewart. Physiology and Histology—Senior: John Elder M'Ilwaine and Hugh Barkley Steen (equal), and John Campbell Rankin. Junior: Samuel Robert Hunter, Walter Phillips, and Frederick William Stewart. Practical Physiology and Histology—Hugh Barkley Steen, John Charles M'Carroll, Walter Phillips, and John Campbell Rankin. Medicine—William Robert Wilson (non-matriculated) and John Thomas Bradley. Surgery—Senior: Annie Helen Crawfurd and Robert Alister Little Graham, B.A. (equal), and John Edmund Clements. Junior: William Hunter Matthew, John Weir West, and William Robert Wilson (non-matriculated). Materia Medica—Charles James Ross, B.A., and Thomas Stratford Logan. Midwifery, Gynæcology, and Diseases of Children—John Edmund Clements, John Thomas Bradley, and William Robert Wilson (non-matriculated). Ophthalmology and Otology—W. Matthew Hunter, Robert Alister Little Graham, B.A., and John Weir West. Sanitary Science—William Matthew Hunter and John Weir West.

PRESENTATIONS TO MEDICAL MEN.—Mr. Herbert Burland, L.R.C.P. Lond., M.R.C.S. Eng., of Finedon, Wellingborough, on April 22nd was presented on his approaching marriage by his friends and residents in that town with an address and a dog-cart as marks of esteem.—At a large and representative meeting held in the parish hall, Sedgefield, on April 23rd, Mr. G. R. Sheraton, L.R.C.P. Edin., M.R.C.S. Eng., of that town, on his retirement from professional life was the recipient of a gold hunting watch, chain, and pendant, and at the same time Mrs. Sheraton was presented with a silver tea and coffee service as tokens of regard.—In appreciation of services gratuitously rendered to the under-mentioned ambulance classes presentations have recently been made to Mr. Thomas M. Martin, M.B. Edin., of Lochwinnoch, of a revolving study chair by the members of the Diamond Jubilee Howwood Ambulance classes, and to Mr. W. Mawer, L.S.A., of Tollesbury, Witham, of a silver-mounted walking stick.—On April 26th, at the town-hall, Wiveliscombe, Somerset, Mr. J. Wyatt Pratt, M.R.C.S. Eng., L.R.C.P. Edin., on the occasion of his silver wedding, was presented by the inhabitants of the town, as a mark of their respect and esteem, with a silver tea and coffee service with tray.—In connexion with the successful ambulance classes conducted at Tow Law, county Durham, during past winter, Mr. Wm. Tiplady, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., the instructor, has been presented by the female class with a china salad bowl with silver rim and service to match, while the male class has given him an eight-day marble timepiece with chimes, as tokens of gratitude for his services to the classes.—On May 9th, on the occasion of closing the Whittington Moor ambulance classes, which have been successfully conducted by Mr. Thomas McClure, M.D. Brux., L.R.C.P. Edin., F.R.C.S. Irel., he was the recipient of a marble timepiece bearing the following inscription: "Presented to Dr. McClure by the members of the Whittington Moor and Sheepbridge Ambulance Class, May 10, 1898."—At a meeting at the Wesleyan school-room, Harrogate, on May 9th, Mr. A. W. H. Walker, M.D. Brux., L.R.C.P. Lond., M.R.C.S. Eng., was presented with an electric medical battery by the members of the Wesley Guild Ambulance Class.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Vaccination Bill.

THE House of Commons has referred the Vaccination Bill to the Grand Committee on Law and to assist in the consideration of the Bill there have been added to the committee the following members, viz.: The Attorney General for England, Mr. Thomas Bayley, Sir Charles Cameron, Mr. Channing, Mr. Chaplin, Sir Charles Dalrymple, Sir Walter Foster, Mr. Hazell, Colonel Long, Mr. T. P. O'Connor, Sir William Priestley, General Russell, Mr. T. W. Russell, Mr. Steadman, and Mr. J. W. Wilson. The committee is not expected to reach the Bill until after the Whitsuntide recess.

HOUSE OF COMMONS.

THURSDAY, MAY 12TH.

Phosphorus Poisoning.

Mr. Pickersgill asked the Home Secretary whether, in accordance with his promise given on the 2nd inst., he had made further inquiry into the case of Cornelius Lean, lately employed at the match factory of Messrs. Bryant and May, who was poisoned by the yellow phosphorus used in the manufacture; whether he proposed to direct that proceedings shall be taken against the occupier of the factory and the factory medical officer respectively for neglecting to give the notices required by section 29 of the Factory Act, 1895; and whether it was intended to prosecute the factory medical officer, under the Registration of Births and Deaths Act, upon a charge of wilfully misstating the cause of death upon the medical certificate.—Sir M. White Ridley replied: The inquiries which have been made reveal, I regret to say, systematic neglect on the part of this firm to comply with the obligations as to reporting cases of phosphorus poisoning. The case appears to me to be a very serious one and I have given instructions for the prosecution of the occupiers. As regards the factory medical officer I cannot see sufficient ground for supposing that, as suggested by the hon. member, he made a wilful misstatement as to the cause of death in the case of Lean. In previous cases, however, of phosphorus poisoning he appears to have committed a breach of the Factory Acts in not notifying the fact to the chief inspector, but as he notified them to the employer and as it seems possible he was under a *bond-fide* belief that that was all that was required of him I have decided not to take proceedings against him.—Sir Charles Dilke asked whether any inquiry was going to be held into the question of the use of yellow phosphorus and whether the former committee could be revived for this purpose.—Sir M. White Ridley replied that he thought it desirable to have an inquiry, but he was not able to say what form it would take.

Vaccination Questions.

Mr. Brigg addressed to the President of the Local Government Board the following five questions, viz.: (1) if he was aware that the council of the Association of Public Vaccinators had declared that the time and trouble required under the proposed Vaccination Bill would be ten times that now paid for, thus increasing the probable cost to the ratepayers from £78,000 per annum to £780,000 per annum, and could he hold out any hope that this largely increased cost would be taken over by the Imperial Exchequer; (2) if he was willing to accede to the wish of the council of the Association of Public Vaccinators that a public vaccinator should no longer be engaged by the board of guardians, but be appointed direct by the Local Government Board, thus removing every vestige of popular control or influence; (3) respecting the Vaccination Bill, if the public vaccinator having received part of his fee on the birth of a child would receive the second moiety of his fee in cases where he instituted proceedings but failed to enforce vaccination; (4) if the refusal of a board of guardians to sanction the costs of prosecutions under the Vaccination Bill would subject them

to imprisonment for contempt of court; and (5) if, in cases of the refusal of parents to allow their children to be vaccinated on account of ill-health or what might appear to them some other good reason, would the power of instituting legal proceedings rest with the vaccinator without any other reference or appeal either to guardians or medical authority.—Mr. Chaplin replied: With regard to the first question I am not aware that the council of the association referred to have made any such estimate of the cost. In any case my view is altogether different from that stated in the question, and I have no belief in the increase suggested. The reply to the next two questions is in the negative. With regard to the next question I am afraid I have nothing to add to the answer which was given on Tuesday to the question of the hon. member for the Chesterfield Division—viz., that I have no right to assume that local authorities will refuse to pay any expenses legally payable by them, and I cannot undertake to reply to hypothetical questions. As to the next question it would not. I think, be correct to say that the powers of a vaccination officer, who, I presume, is the officer intended to be referred to, of instituting legal proceedings would rest with that officer without reference to any other authority. They will be subject to certain conditions. If the child were unfit to be vaccinated through ill-health or otherwise and the parent procured a certificate from a medical practitioner to that effect it would be a bar to proceedings under section 29 of the Act of 1867, so long as the certificate continued in force. Further, the section referred to provides that a parent will be guilty of an offence for not causing the child to be vaccinated only in the absence of a reasonable excuse being rendered by him to the satisfaction of the justices.

The Army Medical Service.

In reply to questions on this subject by Dr. Farquharson and Sir William Priestley Mr. Powell Williams said: The Royal Warrant relating to the Army Medical Service will be issued as soon as certain minor details which involve reference to India can be settled. It will provide for the creation of a Royal Army Medical Corps, the members of which up to the rank of colonel will bear military titles, the present compound title being abolished. Above the rank of colonel the members of the corps will bear the title of surgeon-general, with the precedence and privileges of major-generals of the army, such as they now enjoy.—Major Rasch asked whether it was in contemplation to confer the title of general upon veterinary surgeons as well.—Mr. Powell Williams: No. I do not think the matter has been taken into consideration.

Sickness on the "Britannia."

Lord Charles Beresford asked the First Lord of the Admiralty whether he would lay before the House a return showing the cases of sickness on the *Britannia* between Jan. 1st and May 1st and stating the opinion of the medical officers as to whether this outbreak of sickness was attributed in any degree to improper feeding.—Mr. Goschen replied: No public school publishes lists of schoolboy ailments and there is no reason why the *Britannia* should do so. Surely the noble lord does not wish to alarm anxious parents quite unnecessarily by an official list of such ailments described in technical medical language. But to allay any apprehension which the noble lord's question may have caused, I may state that though there have been a good many cases of mumps and measles, as there have been in many schools during the same period, I am assured that in other respects there has been no exceptional sickness in the *Britannia*. If the noble lord will state to me on what authority he puts forward the innuendo as to improper feeding I will give him an answer.—Lord Charles Beresford said that he had received several letters from the parents of boys on the *Britannia* complaining that a great number of them had had boils and other symptoms of improper treatment and he thought it right to clear up the matter.—Sir Charles Dilke said that he had received complaints in regard to the meat supplied.—Mr. Goschen said that the innuendo was that the medical officers had ascribed the sickness to improper feeding. There was no proof whatever of that suggestion. If cases were brought before him in reference to any defects of diet of course inquiry would be made. He had heard that there had been some inquiry in reference to the meat, but the medical officers reported that there had been no exceptional sickness and no sickness had been ascribed to improper feeding. He regretted that any public statement should unnecessarily alarm the parents of the boys.

Medical Service in Uganda.

Captain Norton asked the Under Secretary of State for Foreign Affairs whether it had been brought to his notice that a recent military expedition in Uganda was actually sent on active service without a medical officer to look after the sick and wounded, and that Captain Dunning, D.S.O. Royal Fusiliers, who was seriously wounded, lived for some days in great agony; further, that there was every reason to believe that his life would have been spared had he received even ordinary medical aid; and would he explain why medical volunteers for this service, who could easily have been obtained in this country, were not called for.—Mr. Curzon replied: The incident alluded to occurred in March, 1895, before the present Government came into office. The arrangements for the expedition in question were made by the officer commanding the troops in Uganda. There were at the time only three medical officers attached to the Uganda staff, none of whom unfortunately was available for the expedition, which could not for military reasons be postponed to admit of volunteers being procured from this country. The number of medical officers on the Uganda staff has recently been raised to 12.

FRIDAY, MAY 13TH.

Milk Prosecution.

Major Rasch asked the President of the Local Government Board whether his attention had been called to the case of a farmer selling milk treated with boracic acid and fined at the Marylebone police-court on Wednesday; and if he would state on what grounds the English producer was punished for selling that which the foreigner placed on the home market without any restriction or liability.—Mr. Chaplin replied: I have seen the report of the case referred to. The offence, as I understand, was of having given a false warranty in respect of milk. The provisions of the law as regards the sale of milk produced in this country and treated with boracic acid apply equally to the sale of imported milk so treated.

Cases of Phosphorus Poisoning.

Mr. Pickersgill asked the Home Secretary if he would inquire into the case of a young woman named Tye, living at 47, Beaufoy-road, Plaistow, who twelve months ago while working at the match factory of Messrs. Bryant and May was attacked by phosphorus poisoning and has since been attended by Mr. Cornelius Garman, the medical officer of the firm, or by his son Mr. Bernard Garman; and, if the notices required by the Factory Act had not been given in this case, would he take steps to enforce the law.—Mr. Pickersgill also asked the right hon. gentleman whether he would inquire into the case of Ellen Cotter, living at 10, Bramley-cottages, St. Leonard's-road, Bromley, E., who in August last, while working at the match factory of Messrs. Bryant and May, was attacked by phosphorus poisoning and had since been attended by Mr. Cornelius Garman, the medical officer of Messrs. Bryant and May, and his son Mr. Bernard Garman; and, if the notices required by law had not been given in this case, would he take steps to prosecute the parties in default.—Sir M. White Ridley replied: These cases are among the cases which I mentioned in my answer yesterday and in which I have ordered a prosecution.

The Vaccination Question.

Mr. Goddard asked the President of the Local Government Board if he would authorise magistrates who had convicted defaulters under the Vaccination laws to give a reasonable allowance of time in which to pay their fines before committing them to gaol or issuing distress warrants on their goods.—Mr. Chaplin said that he was advised that the magistrates had power now to allow time for the payment of the penalty or to allow payment by instalments or to allow securities to be taken, but he (Mr. Chaplin) had no power whatever to give any direction or authority to the magistrates in connexion with their convictions.—Mr. Brigg asked the President of the Local Government Board if he was aware that the feeling of a portion of the people in this country was such that in a printed statement, signed by four metropolitan public vaccinators, it was declared that domiciliary vaccination would render the public vaccinator liable to personal insult, and that they suggested other means whereby witnesses might be present when vaccination was offered; and would he take steps that the suggestion offered, or others for the same purpose, should be adopted as a precaution against such insults.—Mr. Chaplin replied that he was aware of the statement referred to, but he thought it would be quite unnecessary to provide by the Bill that a public vaccinator should be accompanied by a witness on the occasion of his visits.

The Nursing Staff for the "Britannia."

Mr. Ascroft asked the First Lord of the Admiralty whether he was aware that on Jan. 14th a copy of the *Navy and Army Illustrated* was sent to every parent of a cadet on the *Britannia* containing a photograph of the nursing staff at the Britannia Hospital; whether he was aware that the females in such photographs attired in nurses' uniforms were the domestic servants and not qualified nurses; whether any, and if so, what, and on what date, qualified nurses were appointed to attend the cadets of the *Britannia* when sent to the hospital; whether he was aware that on the *Conway* and at most of the public schools a qualified medical matron was engaged to look after the sick patients and due notice was given of such sickness to the parents; and whether he would make arrangements that a similar notice should in future be given when any cadets were invalided at the *Britannia* Hospital.—Mr. Austen Chamberlain replied on behalf of the First Lord as follows: The hon. member has sent me a copy of the paper referred to. It contains not only photographs of the nursing staff of the *Britannia*, but also other photographs illustrative of life on the ship. Though, without time for inquiry, I am unable to say by whom the paper was circulated, I feel confident that it was not circulated officially at the public expense as the question would seem to suggest. The photograph represents the ordinary hospital staff, including a trained sister and a trained female nurse, the former appointed in 1894, the latter added in 1896. Both these ladies had long training in civil hospitals and were specially selected on account of their fitness for the positions. The impression that there were no female nurses probably arose from the fact that this is the ordinary nursing staff for the ordinary sick quarters, whilst in a separate house, which is opened when required for infectious cases, there are trained members of the naval sick berth staff. Great care is exercised in their selection to secure the best men. Notice of any cadet being sent to sick quarters is always given to the parents. Perhaps the House will allow me to add, in reference to questions addressed to the First Lord yesterday, that the following telegram was sent to the captain of the *Britannia* this morning:—"Is there any foundation for complaints as to quality of food?" To this inquiry we have received the following reply:—"No. Absolutely without foundation. Captain, *Britannia*."

MONDAY, MAY 16TH.

Food Analysis.

Mr. A. K. Loyd asked the President of the Local Government Board whether, having regard to the success of the inspector employed by the Royal Lancashire Agricultural Society in 1896 in distinguishing impure from genuine butter by simple inspection, he would consider the desirability of placing the services of a few similarly trained specialists at the disposal of local authorities desirous of such assistance before submitting samples to the public analysts; whether samples for analysis selected by the diligence and self-interest of private purchasers show a higher percentage of adulteration than samples submitted more or less at random, by local authorities; and whether private purchasers had since 1896 shown signs of becoming more alive to their rights and powers under the Sale of Food and Drugs Acts and the Margarine Act, 1887.—Mr. Chaplin replied: I am aware of the proceedings of the inspector referred to, but the Local Government Board have neither the duty nor the power to place specialists at the disposal of the local authorities as suggested. The number of samples submitted for analysis by private purchasers in 1897 exclusive of those submitted by the inspector referred to was about the same as in 1896. They show a higher percentage of detected adulterations than samples submitted by the local authorities.

Remarkable State of Things at Southwark.

Sir Charles Cameron asked the Home Secretary whether his attention had been called to the statement that the remains of between 1000 and 2000 bodies had been found in the crypt of St. George-the-Martyr, Southwark, the coffins in which they had been placed having been burst open by dishonest persons

who had managed to break into the crypt and had stolen the lead; whether he had seen a report by Mr. Wanklyn and Mr. W. Cooper, analytical chemists, to the effect that the atmosphere of the church was contaminated by the passage of air from the crypt to such an extent as to render it dangerously impure; whether he was aware that the vestry refused to incur the expense of removing the remains and were in favour of waiting until the noxious fumes exhausted themselves; and whether the Home Office proposed to take any steps in the matter.—Sir M. White Ridley replied: My attention has been called to this statement. The inspector of burial grounds will thoroughly investigate the matter this week and his report will receive immediate attention.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ALTHORP, C. F. M., M.B. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Bradford Royal Infirmary, vice John Appleyard, resigned.

ASKINS, J. F., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer to Messrs. Tangye's Cornwall Works, Smethwick, Birmingham.

BELDING, D. T., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Mitford and Launditch Rural District Council, vice M. G. Dundas, resigned.

BOISSIER, A. H., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed an Honorary Medical Officer to the Horton Infirmary, Banbury.

BOWES, C. K., M.D. Oxon., B.Ch., has been appointed Medical Officer for the St. Anne's Home at Herne Bay.

BROWN, R., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the First Sanitary District of the Hackney Union.

BURGESS, A. H., M.B., Ch.B. Vict., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Assistant Medical Officer for the Crumpsall Workhouse of the Township of Manchester.

CARSTAIRS, J. L., M.B., C.M. Glasg., has been appointed a Physician to the Glasgow Central Dispensary, vice A. Sloan, resigned.

CAYLEY, F. P., L.R.C.P. Lond., M.R.C.S., has been appointed Clinical Assistant for the Infirmary of the Whitechapel Union.

CHETWOOD-AIKEN, K. C., M.B., C.M. Aberd., has been appointed Ophthalmic Surgeon to the Royal Cornwall Infirmary, vice G. F. Helm.

COOPER, W. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Staveley Sanitary District of the Kendal Union.

CRAIG, J. W., M.D. Glasg., M.R.C.S., has been re-appointed Medical Officer of Health by the Bingley District Council.

DE GRUCHY, C. W., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Caerleon Urban District Council.

DINGLE, C. V., M.B., B.S. Durh., has been appointed Medical Officer for the Middlesborough Corporation, vice J. A. Malcomson.

EDWARDS, H. J., L.R.C.S., L.R.C.P. Edin., D.P.H. Lond., has been appointed an Honorary Medical Officer to the Horton Infirmary, Banbury.

EHRMANN, A., M.R.C.S., L.R.C.P., has been appointed a Clinical Assistant to the Chelsea Hospital for Women, Fulham-road, London, S.W.

GRAHAM, S., L.R.C.P. Lond., has been appointed Resident Medical Superintendent for the District Lunatic Asylum, County Antrim.

HARDWICK, GEO., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer at the Ida Hospital, Leeds.

HILLMAN, G. B., L.S.A., has been re-appointed Medical Officer of Health by the Whitwood Urban District Council.

KEATS, W. J. C., L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed Medical Officer for the Infirmary, and Gordon-road Workhouse, of the Parish of St. Giles, Camberwell.

MACGREGOR, G. R, M.D. Aberd., has been re-appointed Medical Officer of Health (Bingley Outer) by the Bingley District Council.

MARKLEY, H., M.R.C.S., L.R.C.P., has been appointed a House Surgeon at the Ida Hospital, Leeds.

NEWELL, ALFRED GEORGE, M.B., M.C. Glasg., D.P.H. Cantab., L.M. Dubl., has been appointed Assistant Medical Officer at the Three Counties' Asylum, near Hitchin.

OVEREND, W., M.D., B.Ch., has been appointed a Clinical Assistant to the Chelsea Hospital for Women, Fulham-road, London, S.W.

PIERSON, C., M.R.C.S., L.R.C.P., has been appointed a House Physician at the Ida Hospital, Leeds.

SHILLITO, W. A., M.D. Brux., M.R.C.S., has been appointed a Medical Officer by the Bingley District Council.

SIMPSON, G. B., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Lastingham Sanitary District of the Pickering Union.

SMITH LLOYD, G., M.D. Edin., L.R.C.S., has been appointed a Physician to the Monmouth Hospital and Dispensary, vice G. Willis, resigned.

TALBOT, F., M.R.C.S., L.R.C.P., has been appointed a House Surgeon at the Ida Hospital, Leeds.

THOMSON, WM. T., M.B., C.M. Edin., has been appointed an Honorary Medical Officer for the Liverpool Ladies' Charity and Lying-in Hospital.

TURNER, A. F., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Borough of Tewkesbury.

VEALE, H., L.S.A., has been appointed a House Physician at the Ida Hospital, Leeds.

VLIELAND, C. J., M.D. Durh., M.R.C.S., has been appointed Medical Officer of Health by the St. Thomas (Exeter) Urban District Council.

WILLIS, GEO., M.D. Glasg., L.R.C.S. Edin., has been appointed an Honorary Consulting Physician to the Monmouth Hospital and Dispensary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRENTFORD UNION.—Dispenser for the Infirmary, Workhouse, and Schools at Isleworth. Salary £100 per annum, with dinner and tea daily. Applications to the Clerk, Union Offices, Isleworth, Middlesex.

BRISTOL EYE HOSPITAL.—House Surgeon. Salary £80, with board and lodging.

BURTON-ON-TRENT INFIRMARY.—House Surgeon. Salary £130 per annum, with rooms in the infirmary free, also coals and gas.

CARDIFF INFIRMARY.—Assistant House Surgeon and Assistant House Physician, for six months. Board, washing and apartments provided.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY, Chesterfield.—Resident Junior House Surgeon and Dispenser. Salary £50 per year, with board, apartments, and laundress.

COUNTY ASYLUM, Whittingham, Lancs.—Locum Tenens for about five or six months. Two guineas a week.

DONCASTER GENERAL INFIRMARY AND DISPENSARY.—In-door Dispenser and Assistant to the House Surgeon. Board, lodging, and washing provided.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY, Dumfries.—House Surgeon. Salary £50 per annum, with board and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—House Physician for six months. Board, residence, &c., provided and an honorarium of £15 15s. will be granted on the completion of six months' approved service.

EAST SUFFOLK AND IPSWICH HOSPITAL, Thoro'fare, Ipswich.—Senior House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

EGYPTIAN GOVERNMENT.—The School of Medicine and the Kasr-el-Ainy Hospital, Cairo. Medical Officers. Applications to the Director-General, Sanitary Department of the Egyptian Government, care of the Secretary, The Examination Hall, Victoria Embankment, London.

GENERAL LYING-IN HOSPITAL, York-road, Lambeth.—House Physician for four months. Salary at the rate of £50 per annum, with board and residence.

GENERAL HOSPITAL, Nottingham.—Assistant House Physician for twelve months. Salary £50, with board, lodging, and washing in the hospital.

Births, Marriages, and Deaths.

BIRTHS.

CLARKE.—On May 14th, at Forgate-street, Worcester, the wife of Fielding Clarke, M.R.C.S. Eng. and R.C.P. Lond., &c., of a son.

COLEMAN.—On May 15th, at Sutton Bridge, Lincolnshire, the wife of J. G. B. Coleman, M.R.C.S., L.R.C.P., of a daughter.

CUSHNY.—At Ann Arbor, Michigan, on May 1st, the wife of Arthur R. Cushny, M.D., Professor of Materia Medica and Pharmacology in the University of Michigan, of a daughter.

FLEMING.—On May 17th, at 37, Hyde Park-gate, the wife of Samuel Fleming, M.B., D.P.H., Barrister-at-law, of a daughter.

GRIFFITHS.—On May 13th, at Trumpington-street, Cambridge, the wife of Joseph Griffiths, M.D. Edin., F.R.C.S. Eng., D.P.H. Camb., of a daughter.

HALL.—On May 14th, at The Priesthills, Hinckley, Leicestershire, the wife of James A. T. Hall, L.R.C.P., L.R.C.S. Edin., of a son.

NAPIER-JONES.—On May 13th, at Alnbank, Plaistow, the wife of P. Napier-Jones, M.R.C.S., L.R.C.P., of a daughter.

NOBLE.—On May 8th, at The Moorings, Grove-road, Walthamstow, the wife of William G. Noble, L.S.A., of a daughter (Ida Kathleen).

PARKINSON.—On May 12th, at Wimpole-street, W., the wife of J. P. Parkinson, M.D., M.R.C.P., of a son.

TOTHILL.—On May 11th, at Staines, the wife of Frederick C. Tothill, M.B., of a son.

MARRIAGES.

SHARP—RAMSBOTHAM.—On May 11th, at St. George's Church, Leeds, Arthur John Sharp, M.D., of Bagdale, Whitby, to Mary, eldest daughter of S. H. Ramsbotham, M.D., Park-place, Leeds.

STANWELL—EVANS.—On May 12th, at St. Martin's, Stamford, by the Rev. Charles Stanwell, M.A., vicar of Ipsden, uncle of the bridegroom, assisted by the Rev. A. Jones, M.A., vicar of the parish, St. John Stanwell, M.B. Ed., M.R.C.S., fifth son of the late William Stanwell, M.R.C.S., of Rochdale, to Alice, third daughter of Daniel J. Evans, of Stamford.

DEATHS.

FLEMING.—On May 13th, at Ash Tree Villa, Walton, Aylesbury, Robert Martin Fleming, L.R.C.S., L.R.C.P. Edin., aged 35 years.

GRANGE.—On May 12th, at Tring, Herts, Frank Grange, M.D. Lond., D.P.H. Cambridge, of Southampton, aged 32.

OATES.—On May 15th, after an illness, John Harrison Oates, M.R.C.S. Eng., L.R.C.P. Edin., Manor Place, Dewsbury.

SMITH.—On May 13th, at Clifton, Opie Bewley Smith, late Surgeon 7th Dragoon Guards, of The Laurels, Nunnington, Hereford, aged 70.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

FRIDAY (27th). — LONDON POST-GRADUATE COURSE.—King's College 4 to 5 P.M. Dr. Wilkinson: Tuberculosis and Leprosy.

SATURDAY (28th).—ROYAL INSTITUTION.—3 P.M. Mr. J. A. Thomson: The Biology of Spring.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, eithe from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

MEDICAL MARRIAGES.

IT would seem that the ladies who honour the medical profession by making it their own are by no means exempt from the ordinary frailties which beset the human race irrespectively of sex. Love is evidently still able to penetrate the interstices of their scientific panoply and, as usual in like cases, the result is matrimony. At the Madrid Congress the approaching marriage of Dr. Kempner and Miss Susanna Rubinstein, who is an assistant in the Institute for Infectious Diseases at Berlin, was announced; and, according to the French medical press, a similar union is about to take place between Surgeon-Major Castelli of Val-de-Grâce and Madame Chellier, whose distinguished medical career in Algeria has been more than once alluded to in these pages (THE LANCET, Sept. 18th (p. 734) and Nov. 20th (p. 1340), 1897). Dr. Castelli left the Republican Guards in order to join the Madagascar Expedition, where his services earned him the Cross of the Legion of Honour. His bride, who is the first native of Algeria to obtain

e diploma of Doctor in Medicine, is known throughout the wilds Kabylia as the "tebiba" or female physician. It is in a eat measure due to her perfect knowledge of the language that e has been enabled to gain the entire confidence of the uncivilised habitants. A French journalist, commenting on this auspicious arriage, says: "If medical ladies do not easily acquire large actices it is, at all events, very pleasant to find them for the most rt happily married. At the present moment we can call to mind e names of four practitioners who have selected their wives from e ranks of the medical profession—to wit, Drs. Déjerine, Jacques rillon, Sollier, and Pillet."

AN IMPROPER CIRCULAR.

To the Editors of THE LANCET.

s,—May I ask your opinion of the enclosed circular which has addressed broadcast to my patients and also other medical men's nts in this district. The enclosed copy was handed to me by a nt of mine who had never seen the writer, to say nothing of his ng never attended her. I await your next issue (containing your ion) with interest. I am, Sirs, yours faithfully,

y 13th, 1898. MEDICUS.

[ENCLOSURE.]

DEAR SIR OR MADAM,—It affords me much pleasure to inform ou that owing to pressure of work I have been compelled to place fully qualified medical gentleman to reside at Ll——.

I have secured the services of Dr. S——, who holds the highest redentials, and I feel justified in believing that implicit confidence n him will not be misplaced.

Dr. S—— will reside at Mr. L——'s, station master, A—— House, l——.

Either Dr. S—— or I will attend at Mr. R——'s, Post-office, C——, ily, at 3 P.M.

I beg the honour to remain, yours respectfully,

—— ——, M.R.C.S., L.R.C.P.

We think the circular an improper one to be sent by any medical n to persons who are not on his own books or his own undoubted ients. The dissemination of such circulars truly makes of the dical profession a trade, and a trade not over particular as to nners.—ED. L.

THE HABITUAL DRUNKARDS ACT.

To the Editors of THE LANCET.

s,—The new Habitual Drunkards Act seems only to provide for stention of those who do some criminal act, but there are very r habitual drunkards, men and women, whom we ought to have r to put away for their own and others' good, just as we do other ses. Cannot something be done to supply this omission?

I am, Sirs, yours faithfully,

rley-street, W., May 15th, 1898. HEYWOOD SMITH.

THE LITERATURE OF TROPICAL DISEASE.

To the Editors of THE LANCET.

s,—Will some of your readers who have served in the West Indies n India refer me to the best English works on diseases of tropical ates? I have Scheube in German, and Laveran, De Brun, and in French, and only Maclean's Diseases of Tropical Climates in sh. As our army is likely in the near future to get a taste of signing in the tropics I should much like to read the best English s on the subject. Especially would I like to be referred to some or works on military hygiene suitable for a combatant officer quainted with tropical service.

I am, Sirs, yours faithfully,

y, N.Y., April 23rd, 1898. WILLIAM WOTKYNS SEYMOUR.

"THE JOHN PAGE HENTSCH APPEAL."

To the Editors of THE LANCET.

s,—I beg to acknowledge the sum of 3 guineas from Sir T. Smith, ford-place. The total amount received is £34 2s. 6d. In closing st I beg to convey the thanks of the widow to those who have rded donations and to you for the use of your valuable space.

I am, Sirs, yours faithfully,

Brixton-road, S.W., May 17th, 1898. G. DAVID KNIGHT.

TO WEARERS OF THE PINCE-NEZ.

To the Editors of THE LANCET.

s,—It may be always worth while to take note of even a minor ent to the eye, more especially when this may as easily be a serious s it is preventable. Within my own experience I have more than met with cases in which more or less damage has resulted to the ll or external canthus by the dragging up against it of the bar which cting backwards from the frame of the ordinary pince-nez serves ep them folded. Of course one is aware that this accident must re likely to occur when a cord is worn as usual and also that it t happen with some forms of pince-nez; but it seems to me a pity the more common form of glasses worn should not be rendered able of inflicting such an injury by this bar being placed in front e folder instead of at the back, where, I take it, it would be quite ficient. The simplicity of the mode in which the injury may and of its remedy may justify this note.

I am, Sirs, yours faithfully,

y 18th, 1898. M.D. LOND.

PUERPERAL ECLAMPSIA.

To the Editors of THE LANCET.

SIRS,—I shall be obliged to any of your readers for references to puerperal eclampsia occurring at an early period in pregnancy and at a late period after delivery. I am, Sirs, yours faithfully,

May 18th, 1898. R. C.

THE NOTORIOUS QUACK TOWNSEND.

"PROFESSOR" W. H. TOWNSEND is well known in the west of England. He apparently finds that the demands of his "practice" are too much for him to carry on alone and he has therefore had the insolence to write to a firm of medical agents the following letter. We need not say that the agents refused to have anything to do with him.

[COPY.]

King Alfred Temperance Hotel, Taunton,

April 21st, 1898.

DEAR SIRS,—Can you place me in communication with a Lady Doctor who is disengaged and who is anxious to be employed in a large practice? Kindly let me know by return. I enclose two or three articles which you may enclose in any letter you may write for me to a Lady Doctor. Her age must be 23, 24, or 25, and please state her experience, &c., if you write me for any Lady.

Yours truly,

(Prof.) W. H. TOWNSEND.

You may place me in communication with a Gentleman Surgeon, M.R.C.S., as well. I have not quite made up my mind who to engage yet.

"Professor" Townsend enclosed a circular with sundry excellent maxims at the head, of which we recommend the following one to those who consult him: "Who knows not and knows not that he knows not is a fool—shun him." We do not suppose that the "Professor" will get either a "Lady Doctor" or a "Gentleman Surgeon."

Subscriber (Brighton).—1. We think that such pamphlets when freely circulated to the public should not bear the name and medical titles of the medical officer. We note, however, that in this particular instance the address is properly absent. 2. The committee should, of course, consult their medical man. 3. If he objects to the publicity they should not publish his name.

Telegraphs.—Our correspondent can get information concerning the colonial medical appointments by making inquiry at the Colonial Office. There are always many applicants for the pleasanter berths, but the pay is not good. Concerning the telegraph ships we advise him to write to Messrs. Siemens Bros. and Company, Limited, of Woolwich, Kent.

M.R.C.S., L.R.C.P., and several others.—We saw the curious error, of course. It was in the majority of the papers, great and small. Considering what are the characteristics of Cheyne-Stokes breathing we think the blunder resulted in a fortunate expression.

B. A. M. gives no permanent address. The system of which he writes is a quack system which cannot be too highly condemned as dangerous and ineffective. He should consult his medical man.

L.R.C.P. has himself named the best treatises. We have nothing to add to his list, but we are doubtful whether it would be wise to embark on such an exhaustive course of reading all at once.

An Old Subscriber is strongly recommended not to give the testimonial in question unless he receives a guarantee that it will not be used as a public advertisement of the article.

R. F. W.—Jamieson's "Diseases of the Skin" is quite suitable. Malcolm Morris's "Diseases of the Skin" is also a very good little book.

R. J.—We do not think the information is forthcoming, but application might be made to the Registrar-General.

Verax.—We have nothing to add to our former answer.

During the week marked copies of the following newspapers have been received: *Dewsbury Reporter, Sheffield Telegraph, Newcastle Leader, New Ross Reporter, Southampton Times, Weston-super-Mare Gazette, Leicester Post, Ayrshire Post, Oban Times, Times of India, Pioneer Mail, Shipping Gazette, Hastings Times, Worthing Gazette, Lowestoft Standard, Westmeath Examiner, New Age, Builder, Manchester Courier, Liverpool Daily Post, Glasgow Herald, Citizen, Architect, Scotsman, Bristol Mercury, Sussex Daily News, Tonbridge Telegraph, Eastern Daily Press, Salisbury Journal, Southampton Observer, Yorkshire Post, Eastern Morning News, Norfolk Chronicle, Birmingham Gazette, Derby Express, Leicester Express, South Wales Daily News, Leeds Mercury, Brighton Gazette, Sanitary Record, Mining Journal, Local Government Chronicle, City Press, Reading Mercury, Hertfordshire Mercury, Local Government Journal, Derbyshire Times, Surrey Advertiser, Grimsby News, Bedfordshire Advertiser, Clifton Chronicle, Banffshire Advertiser, European Mail, Burton Chronicle, Kelso Mail, Tyrone Constitution, Malvern News, Essex Newsman, Thanet Guardian, Alnwick Gazette, Devizes Gazette, West Middlesex Herald, &c., &c.*

Communications, Letters, &c., have been received from—

The Ingleby Lectures
ON
EXTRA-UTERINE PREGNANCY.

ivered at Mason College, Birmingham, on May 11th, 18th, and 25th, 1898,

By JOHN W. TAYLOR, F.R.C.S. Eng.,
IDENT OF THE MIDLAND MEDICAL SOCIETY; SURGEON TO THE IRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN; CONSULTING SURGEON TO THE WOLVERHAMPTON HOSPITAL FOR WOMEN, ETC.

LECTURE I.

Delivered on May 11th.

TBAL PREGNANCY AND ITS EARLIER COMPLICATIONS.

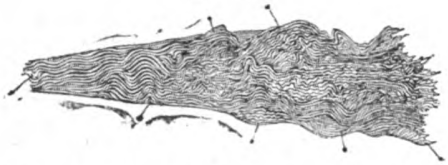
I.—Introductory and Historical.

R. DEAN AND GENTLEMEN,—On looking over the whole ain of practical medicine there is perhaps no one disease h during recent years has so notably emerged from urity—about which more has been learnt and in the ment of which more has been achieved—than that which ve taken as the subject of the Ingleby Lectures for

Some twenty years ago the advance of which I have en received its first impetus from the initial work of one y predecessors in this lectureship—Mr. Lawson Tait—from the remarkable book of Dr. Parry, which was led on the records of 500 cases and still remains a d of patient investigation and labour. Although several tions had been undertaken for the removal of an extra-ne fœtus at or beyond the normal period of gestation at least one case of early extra-uterine gestation had successfully relieved by vaginal section,[1] no operative had been made at this time to control the hæmorrhage o rupture of the sac and to save the victim of fatal peritoneal bleeding; and Dr. Parry when dealing with condition wrote in words which have been frequently d, but may even still bear repetition: "A bleeding l through which the red stream of life is rushing can be ligated. A gangrenous limb which is ying its possessor by sending its poisonous emana- to the remotest regions of his body can be ampu- A cancerous breast which is sapping the vitality victim hour by hour can be removed with the prospect porary relief. An aneurysm that places life in constant dy can often be cured by proximal or distal ligation. umultuous motion of a heart organically diseased may leted till nature restores the balance, after which the may enjoy a long and even a useful life. Even is now counts its many cures, but here is an accident may happen to any wife in the most useful period of xistence, which good authorities have said is never and for which, even in this age when science and art of such high attainments, no remedy, either medical or al, has been tried with a single success. From the of the eleventh century, when Albucasis described st known case of extra-uterine pregnancy, men have ess watched the life ebb rapidly from the pale victim accident, as the torrent of blood is poured into the inal cavity, but have never raised a hand to help her. this is an anomaly and it has no parallel in the whole of human injuries. The fact seems incredible, one life is saved by active interference it may be hantly pointed to as the first and only instance of d on record. In the whole domain of surgery—for not look to other than surgical measures under the stances—there is now left no field like this. ..... ly remedy that can be proposed to rescue a woman these unfortunate circumstances is gastrotomy—to e abdomen, tie the bleeding vessels, or to remove the ire."

definite appeal or challenge to surgery for the rational ent of tubal rupture, written in 1875, and repeated ore or less force by many of the older gynæcologists et lacked the courage to act upon their convictions), was finally taken up by Mr. Tait, who deliberately operated for tubal rupture in 1883. His practice was soon followed by other surgeons, both at home and abroad, and the era of surgical treatment for intra-peritoneal hæmorrhage due to tubal rupture was definitely started. How fertile this has been, how many lives have been saved by this advance in surgical treatment, it is almost impossible to estimate, but we know that no important operation of modern surgery has been more successful than this, and the work which has been done has led, and is still leading, to a better knowledge of the disease, its consequences and complications, so that every few years since this date have brought increase of light, increase of resource and increase of promise for the future. The lesions found and specimens removed as a result of operation during the earlier period of gestation soon established the fact that all cases of extra-uterine pregnancy (as Mr. Tait had already contended) were originally tubal or interstitial and therefore that the varieties which had been described by former observers could all be traced to a tubal origin. Later, one of these varieties, the subperitoneo-pelvic or subperitoneo-abdominal form of "broad ligament pregnancy," was very fully investigated and described by Dr. Berry Hart and Mr. Carter, and their monograph remains our standard of reference for the general method in which the peritoneum may be displaced by the growth of this variety and for the actual conditions found in two examples. Later still Mr. Bland Sutton drew our attention to the condition known as "tubal mole" and "tubal abortion" in which the Fallopian tube affected by the misplaced pregnancy is found to contain an apoplectic ovum instead of a growing fœtus. Following up these investigations I showed before the British Gynæcological Society in 1894 that the abdominal ostium of the tube in these cases commonly remained open and that intra-peritoneal hæmatocele whenever it was found could usually be traced to the blood-drip from the fimbriated end of a tube in which a mole of pregnancy had formed, the special peculiarities assumed by such hæmatoceles being considered and explained. These observations and conclusions were confirmed by those of Dr. Cullingworth, and the existence of intra-peritoneal hæmatocele—a definite tumour due to intra-peritoneal hæmorrhage—(which had been apparently denied by some authors) has not only been again established, but its special relation to tubal mole and to bleeding from the unruptured tube is now accepted by the best of modern writers.

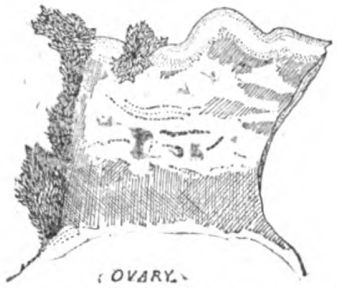
There are still other points in connexion with the subject of extra-uterine pregnancy that demand some further investigation and fuller explanation. One of the most important of these is the exact history and condition of the variety known as abdominal or ventral. That this is a direct secondary development of tubal pregnancy was held by myself in the report of a case which I brought before the Obstetrical Society in 1891 and again before the British Gynæcological Society in 1892. It was exhaustively proved also in Dr. Croom's case by the post-mortem examinations and reports of Dr. Clarence Webster, but the cases were of somewhat different type and have failed to leave sufficient impress on the current literature and teaching of the day. In the course of these lectures I hope to be able not only to show that this abdominal or ventral pregnancy is not, as Mr. Tait and Mr. Bland Sutton have held, a mere secondary result of the broad ligament form, but that it is a variety having only very rarely any connexion with broad ligament pregnancy, a variety with subsidiary modifications, under one or other of which it is possible to group all the cases of this kind that have been hitherto recorded. I shall also endeavour to reopen certain questions connected with my subject which, although more or less dogmatically settled by past observers, appear to my mind to be insufficiently explained and to need for their consideration an open mind and a wider knowledge. To this part of my subject belongs the question of causation.



II.—Causation.

Every pregnancy is the result of the impregnation of the ovum of the female by the spermatozoon of the male and the normal place for the development of the impregnated ovum is the cavity of the uterus, while the channel through which the ovum must pass from the ovary in order to gain the uterine cavity is the Fallopian tube. The tube may be regarded as specially fitted to be this channel for the reception and transit of the ovum. The delicate plications of its mucous membrane, seen best when floated under water,

[1] homas, Feb. 7th, 1875; New York Medical Journal, June, 1875 3900.



as in the accompanying illustration (Fig. 1), form the lightest and most delicate of resting-places, while the innumerable cilia of its epithelium, waving always towards the uterus, tend to sweep the ovum onwards and outwards. These plications with their waving cilia are not

FIG. 1.

confined to the tube itself, but are continued over the border at the fimbriated extremity into the peritoneal cavity and usually stretch in unbroken line from the tube to the ovary itself. Sometimes this "ovarian fimbria" is remarkably full and broad (as in Fig. 2), while accessory

FIG. 2.

fimbriæ, both around the abdominal ostium and on the sides of the broad ligament, complete an apparatus for the direction of the ovum which must cause a marked and ceaseless current from the ovary to the tube. Rarely an accessory ostium is found as in the illustration. In this way the ovum when shed is swept into the abdominal ostium of the Fallopian tube; but when the ovum has entered the tube it may be considered as doubtful whether its progress is continuous and uninterrupted until it enters the uterine cavity. The adult Fallopian tube is convoluted and at every bend or turn is bound down by fibrous bands beneath the serous covering (Fig. 3). Each of these forms a ridge or elevation

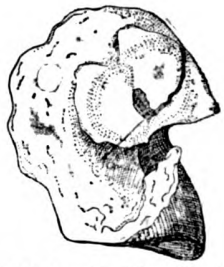


FIG. 3.

within the tube which must be somewhat difficult to pass and the progress of the ovum is probably retarded at each bend of the tube by the presence of these bands. Whereabouts in its passage does the ovum meet the spermatozoon and become impregnated? Dr. Ingleby, in whose honour these lectures were instituted, suggested in 1834 that there was no fixed place where impregnation occurred, but that anywhere during its descent, whether in tube or uterus, it was possible for the conception to take place. More modern writers, on the other hand, have usually assumed that normal impregnation occurs only in the uterus. Mr. Tait writes: "The uterus alone is the seat of normal conception," and "the function of the ciliated lining of the Fallopian tube is to prevent spermatozoa from entering them"; while Mr. Bland Sutton states: "It is reasonable to believe that fertilisation normally happens in the uterus, but when it occurs in the tubes it is accidental and tubal gestation is the consequence." The only ground for this belief appears to be the fact that the normal attachment and development of the impregnated ovum is within the cavity of the uterus.

It was formerly held that the direction of ciliary movement in the uterus was from the cervix to the fundus, while that in the Fallopian tubes was from the fimbriæ to the uterus; therefore that the passage of the spermatozoon was helped by ciliary movement towards the fundus of the uterus, while the passage of the ovum was similarly assisted from the fimbriated end of the tube toward the fundus. On this hypothesis it was reasonable to suppose that the fundus was the normal meeting place of the spermatozoon and the ovum and that here normal inpregnation alone took place. But during recent years the direction of ciliary movement within the uterus has been ascertained to be quite otherwise, both in animals and women, an examination of the freshly extirpated uterus by Hofmeier proving that the direction of this movement is from the fundus to the cervix and therefore that its direction throughout from the fimbriated end of the Fallopian tube to the neck of the uterus is wholly in a downward and outward direction. This being the case, the function of ciliary movement cannot be (as Mr. Tait supposes) to prevent the entrance of spermatozoa or none could enter the uterus. On the contrary, it has been directly proved that the active movements of the spermatozoa are quite sufficient to carry them against the current of ciliary movement and human spermatozoa have been actually discovered in the Fallopian tubes after extirpation of the appendages (Dührssen). Many years ago (in 1838) Bischoff and Barry discovered spermatozoa on the surface of the ovaries of bitches some time after copulation.[2] Mr. Tait, referring to these and similar researches on the lower animals, writes as follows: "Spermatozoa have been found high up in the cornua of the bipartite uteri and these cornua have been erroneously supposed to be Fallopian tubes whilst they are nothing of the kind. The Fallopian tubes do not exist save in the higher orders of animals, who have assumed the upright position." This criticism unfortunately appears to be founded on error. The Fallopian tubes do exist in the lower animals and are very perfect structures in the dog and sheep and heifer, as I have proved by personal dissection. That of the dog (or bitch) may be seen in the accompanying illustration (Fig. 4).

FIG. 4.

Horn of uterus of bitch (recently delivered). Ovarian chamber laid open; Fallopian tube coursing over ovarian chamber; bristle passed into fimbriated end of tube.

It proceeds from one side of the cornu of the bipartite uterus (which is otherwise completely closed) and after a winding course over the ovarian chamber—a membranous sac enclosing the ovary—it opens by a well-marked fimbriated extremity within the ovarian chamber itself. Consequently, any spermatozoa found on the surface of the ovary must have passed, not only through the cornu of the uterus, but through the whole length of the Fallopian tube also.

Dr. Strassmann, who has quite recently collected considerable evidence on the subject of conception, writes as follows: "Fructification, the union of the ovum with the spermatozoon, takes place in the Fallopian tube probably at the fimbriated end and immediately after the exit of the ovum from the follicle (Bischoff-His). Accordingly, we may draw the conclusion that each pregnancy begins as an extra-uterine one and that an extra-uterine pregnancy is a consequence of retarded movement of the fructified ovum." This

[2] Parry, p. 45.

probably goes too far. The uterine ostium of the Fallopian tube when contracted cannot favour the ingress of spermatozoa to the tube and the entrance (or not) of spermatozoa must depend largely on the dilatation (or contraction) of the ostium. Sometimes the passage from the uterus to the abdomen must be very free and especially so when the cervix is dilated. In six cases Döderlein experimentally injected coloured solutions into the dilated uterus before its removal by vaginal hysterectomy. In all but one of the cases the solution passed into the peritoneal cavity.[3] On the other hand, the frequent use of intra-uterine injections without abdominal disturbance resulting appears to show that this open and previous state of the tubes is not a common or invariable condition. That the normal tube admits the entrance of spermatozoa, but is not the special "receptaculum seminis," seems proved by the researches of Professor Dührssen, who in his Vaginal Cœliotomies for Retroflexion in Married Women has frequently pressed a cover-glass against the abdominal ostium and examined for spermatozoa. In most of his investigations he met with a negative result, but in some spermatozoa were recognised although degenerated and motionless.[4] The truth evidently lies between the two extremes. We may hold with reason that here is no evidence whatever for the belief that the seat of normal impregnation is limited to the cavity of the uterus, while the facts which are known concerning the invasion of the tubes by spermatozoa unmistakably point to the conclusion that normal fructification of the ovum may occur at any stage of its passage from the ovary to the uterus. But if normal impregnation often occurs within the Fallopian tube the latter has an important function which at present is altogether disregarded. If the tube has to convey the fructified ovum as well as the unimpregnated ovule into the cavity of the uterus other forces than the ciliary movement may be necessary and any mechanical impediment to the delivery of the ovum from the tube into the uterus may be a cause of misplaced pregnancy. The fructified ovum is subject to definite growth (in the second week it is from 3 to 6 mm. in diameter) and though it probably soon passes from the tube into the uterus it is evident that any want of development in the tube, any permanent contraction, any swelling of the mucous membrane, any abnormal length of the tube, any extra weight or impaired mobility of the ovum at its entrance to the tube, any failure of muscular power, or any interference with the peristaltic action of the tube, if this be needed for propulsion of the ovum, may increase the tendency towards a tubal instead of a uterine "settling" of the ovum. It has been objected by Mr. Bland Sutton that tubal pregnancy cannot be explained by obstruction to the transit of ova because the "oosperm" (fructified ovum) is more often retained in the wide ampullary section of the tube than in its uterine segment, and if delay or stoppage during transit of the fructified ovum always depended on the inadequate size of an otherwise normal tube the criticism would have considerable or even fatal force. This can only be one among many causes for delay and it is probably a rare cause. Still it is interesting to note that in a special class of cases, the cases of early rupture in which the tube, as we shall see, is ill-developed or somewhat atrophied, it is precisely at this point, or just outside the uterine segment of the tube, that arrest most frequently takes place and the pregnancy develops. On the other hand, at the outer extremity of the tube, near the expanded ostium, where not infrequently a tubal pregnancy is found, it is evident that a totally different cause or set of causes may account for retarded progress or arrest of the impregnated ovum and consecutive attachment. Here the in-going tubal current, which, whether due altogether to the movement of the cilia or not, has been proved experimentally to exist, may lack the power to sweep the oosperm into the lumen of the tube; the ovum itself, if prematurely fertilised, may soon increase in size and weight and the fimbriated extremity of the open tube may fail to surround or grasp it sufficiently for any muscular (peristaltic) action to be applied to it. That such an action of the tube is possible seems proved by the history of some of the cases of so-called "tubal abortion" which occur in this situation. In these cases after attachment of the fructified ovum and some development and after the size of the ovum has been increased by sub-chorionic bleeding the tube may contract on its contents, separate the attachments, and extrude or "vomit" the mole of pregnancy out of the tube into the pelvis. If the tube possesses this reverse action when the conditions are altogether unfavourable for any movement in the ovum it is surely reasonable to suppose that when the conditions are favourable, when the ovum is smaller and there is no attachment, natural peristalsis occurs in the normal direction from the tube towards the uterus. The activity (or otherwise) of this, depending, as it must, not only on the part of the tube involved but also on the nerve influence and on the development of the muscular coat, cannot fail to have its bearing on the progress of the ovum. In other cases, perhaps in the majority of cases, the arrest of the fructified ovum is probably determined by swelling of the mucosa. It is in the middle and outer portions of the tube and not towards the uterine segment that the wonderful plications of its mucous membrane are most luxuriantly developed and any source of swelling affecting these would naturally attain the most obstructive power in the central portion of the tube. Such a positive source of obstruction is described in detail by Dr. Webster as produced by the occasional formation of a special swelling and growth in the deeper layers of the tubal mucosa, a swelling which somewhat closely simulates that of the uterine decidua. With perhaps questionable wisdom Dr. Webster speaks of this as the tubal decidua—questionable, for no one has been able to detect in the pregnant tube anything macroscopically approaching to the decidual membrane of the uterus, but there can be no doubt that his sections and specimens, as well as those of some German writers, show changes in the mucosa of the tube, which, whether strictly analogous to those taking place in the uterus at the formation of the decidua or not, do form definite localised swellings which may mechanically arrest the progress of the ovum during its journey down the Fallopian tube.

Mr. Tait and some other writers have held that a pre-existing desquamative salpingitis is the cause of ectopic gestation and that most cases of extra-uterine pregnancy have a previous history of inflammatory mischief of the uterine appendages. I have not found this in my own experience. In 37 cases no certain evidence could be elicited of any pre-existing inflammation and the patients were remarkably free from any suspicion of gonorrhœa or syphilis. Mr. Bland Sutton writes: "In many instances I have failed even after the most careful microscopic examination to find any evidence of old salpingitis or loss of epithelium"; and again, "The evidence now indicates that a healthy Fallopian tube is more likely to become gravid than one that has been inflamed." Mr. Tait's opinion is avowedly grounded on the theory that the impregnated ovum requires a raw, denuded, or wound-surface for its "settling" and that this is normally provided in the uterus through the process of menstruation in which the epithelial coat is shed. Extended consideration and investigation have not tended to confirm our belief in this theory. On the contrary, the more it is considered the greater are the objections which can be urged against it. As Clarence Webster and Strassmann have pointed out, menstruation is by no means a necessary precursor of pregnancy. Pregnancy may take place in a girl who has never menstruated, in a woman who is suckling and has not menstruated since her "lying-in," in women who have amenorrhœa from other causes, as from chronic phthisis and anæmia. Very occasionally, too, we meet with fertile women who have only very rarely menstruated and in whom no history of a period is found corresponding to the onset of pregnancy. The very facts, or supposed facts, behind the theory are now disputed. It is very questionable whether the epithelium is removed to any extent by the menstruation and the more recent observations appear to show that no true wound-surface is provided by this process for the engrafting of the ovum.

The ante-menstrual period, when the monthly swelling and congestion of the uterine mucous membrane attains its maximum, is now with more reason regarded as affording the best conditions for the "settling" of the ovum; in fact, each monthly swelling of the mucous membrane of the uterus may be regarded as the tentative preparation for a possible pregnancy. If the "down-wandering" ovum is fertilised the swelling increases and a uterine decidua is formed. This catches and embeds the wandering ovum. No menstruation occurs. The woman is pregnant. If, on the other hand, the ovum be not fertilised the tentative swelling is carried no further, menstruation begins, and the swelling of the uterine mucous membrane dwindles away by and during the process of menstruation. For the time being the chance of pregnancy is lost. This view is strongly supported by the evidence derived

[3] Centralblatt für Gynäkologie, 25.
[4] Archiv für Gynäkologie, Band 54, Heft 2, p. 297.

from the current practice of nearly all large gynæcological clinics. If a patient has menstruated within two or three weeks the sound, if necessary, is passed without hesitation, and this without a single known instance of early miscarriage resulting, while if the menstrual period be almost or altogether due passage of the sound is by no means free from danger in this respect. Instead, then, of menstruation fitting the uterus for the reception of the ovum it is more probably a sign that the fitting period has passed. The period, I repeat, of the ante-menstrual swelling, when the sides of the uterus are in apposition, is that most favourable for the "settling" of the ovum. If this reasoning be true as regards the uterus it tends to greatly increase the importance of the researches of those who have detected decidua-like swellings of the tubal mucosa. Whether this tissue has any specific action is probably very questionable, but the swollen mucous membrane may undoubtedly sometimes arrest the impregnated ovum and so determine the site of its development. Very rarely a tubal polypus has been found on the uterine side of a tubal pregnancy. One case of this kind has been recently described in detail by Professor Dührssen (Fig. 5). The little polypus appears to have

FIG. 5.

From Dührssen.

formed a perfect ball valve to the uterine end of the tube, the passage of the tube from the uterus to the ovary being free from difficulty, while that from the ovary to the uterus was absolutely stopped by the polypus. On the ovarian side of the polypus the pregnancy had developed.

Again, a tubal pregnancy has been found on the ovarian or outer side of a myoma, the passage into the proper uterine cavity being evidently blocked by the myoma. Dr. Cullingworth has quite recently shown a very valuable specimen of this kind at a meeting of the Obstetrical Society of London. These cases, although too rare perhaps to warrant any general deductions from them, tend undoubtedly to strengthen the argument of mechanical obstruction as an important factor in causation. Sometimes fixation or stretching of the tube is found in connexion with a tubal pregnancy and then may reasonably be regarded as having been a source of delay or obstruction to the passage of the impregnated ovum. In three of my cases tubal pregnancy was found associated with ovarian cystomata—one of them a dermoid of considerable size—and in all of these the tube had been fixed or distorted by the growth of the cyst or by accompanying adhesions. To briefly recapitulate. Normal impregnation of the ovum is not limited to the uterus but may occur anywhere in the Fallopian tube or immediately on the exit of the ovum from the ovary. Normal attachment and development is limited to the uterus only. Abnormal arrest of the impregnated ovum—whether mechanical or special—in its progress towards the uterus is the determining factor of a misplaced pregnancy. An extra-uterine pregnancy, therefore, is the consequence of the permanent arrest of a fructified ovum in its passage from the ovary to the uterus. Theoretically this arrest may occur: (1) in the ovary; (2) in the abdominal cavity between the ovary and tube; (3) within the tube; and (4) between the tube and the uterus.

The first is theoretical only. It is possible, but absolute proof of such a pregnancy seems still to be incomplete. There are, as we shall see, conditions of intra-ligamentary position of the ovum, and also of encapsulated hæmatocele around the ovum, in both of which the ovary may form part of the outer wall of the sac containing the pregnancy. Later this becomes stretched and thin, owing to inside pressure from the growing pregnancy and sections of the sac and outer wall discovering the presence of ovarian tissue may wrongly lead to the conclusion that the pregnancy is ovarian. The conditions described need careful elimination before any pregnancy can be held to be strictly ovarian in origin. The second—"arrest in the abdominal cavity between the ovary and the tube"—is probably always immediately fatal to the unprotected ovum and consequently may be eliminated from discussion. The fourth point of arrest—between the tube and uterus—may quite as correctly be regarded as arrest in the uterine portion of the Fallopian tube, so that for all intents and purposes we have to do at the outset with one kind, the third kind, only—arrest within the tube, or tubal pregnancy. All other varieties are later developments of tubal pregnancy and are caused by secondary invasion from the Fallopian tube of some other tissue or organ. These are conveniently divided into three groups or divisions: (1) the tubo-abdominal (abdominal or ventral) pregnancy, in which there is secondary invasion of the abdomen; (2) the tubo-ligamentary (mesometric or broad-ligament) pregnancy, in which there is secondary invasion of the broad ligament and sub-peritoneal tissues; and (3) the tubo-uterine, or interstitial, pregnancy, in which there is secondary invasion of the uterus. These will be considered in detail after the earlier stages of tubal pregnancy have been dealt with.

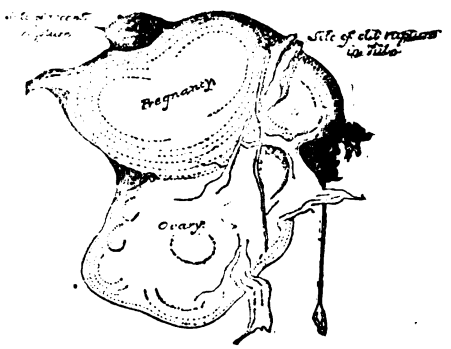
Time will not allow me to deal as I should like with the earliest life-history of the growing tubal pregnancy. I must pass over much of this with the merest notice that its growth is attended by very marked increase in the vascularity of the tube and mesosalpinx and that a decidua, so far as we know, invariably forms in the uterus.

III.—The Earlier Disturbances of Tubal Pregnancy: (1) Early Rupture of the Tube; (2) Tubal Mole; and (3) Later Rupture of the Tube.

Most tubal pregnancies are abortive. Some become so at a very early stage, the pregnancy resulting in early rupture of the tube. Others grow for a few weeks and then are injured by hæmorrhage from their own vessels, a tubal mole forming within the unruptured tube. Others again attain a much greater degree of development and then cause rupture of the tube, perishing in the process either directly from the hæmorrhage and dislocation or indirectly from the death of the patient or from the hand of the surgeon who removes the pregnancy. These cases will be considered under the heading of later rupture of the tube. It is only the minority of cases in which these dangers are averted by some more or less accidental method of growth and of extrusion from the tube and in which the pregnancy goes to term within the organism of the mother.

1. *Early rupture of the tube* from a pregnancy of from two to five or six weeks' standing is a special phenomenon of extra-uterine pregnancy which has not as yet received the recognition and consideration it deserves. As a disease or accident it stands quite alone. There is no warning of danger, there are often no physical signs, there is no symptom before that of sudden and copious bleeding, and any history of pregnancy is either altogether wanting or is represented only by an account of menstruation delayed for one week or even less. A good example of this class of case may be taken from Mr. Tait's book (p. 18): "On November 2nd, 1889, at 1.30 P.M., Mrs. — was seized with pain in the abdomen, followed by vomiting and faintness. Dr. Guthrie Rankin was called in; the pain was relieved by an opiate, but collapse occurred and death ensued at 9 o'clock the same evening. She was the mother of three children, suckling the youngest, aged seven months, of good constitution, with no history of previous illness. At the post-mortem examination the abdomen was found full of clots estimated at from 70 to 80 oz. The left Fallopian tube presented an ovoid swelling which had been ruptured and was full of blood-clots; on examination this swelling proved to be a tubal pregnancy of certainly not more than five weeks. The rupture which caused death was not larger than a pea." In this case death ensued after an illness of only 7½ hours' duration, the fatal result being exceptionally sudden. The more usual duration is from 12 to 48 hours. Two cases from my own practice will illustrate this portion of my subject.

Mrs. A, aged thirty-three years, having one child six years of age, had been menstruating regularly for upwards of a year until Dec. 23rd, 1891, that being the date of the last normal period. On Jan. 20th there was a very slight hæmorrhagic discharge, but menstruation did not follow. On Jan. 28th she was troubled with abdominal pain and in the evening she was sick, and the pulse, which had been about 80, rose to 120. She passed a fair night, but was again sick in the morning and the pulse rose rapidly to 140. I saw her in consultation with Dr. A. V. Bernays at 11 A.M. She was then faint and pallid, but fully conscious, with a quick pulse and distended abdomen. A soft doughy mass was to be felt filling the pouch of Douglas behind the uterus. I



diagnosed the condition as due to ruptured tubal pregnancy and advised operation. When this was done two hours later the patient's condition had become exceeding grave. As I opened the abdomen the blood gushed out like the fluid in ascites and it was evident that the distension of the abdomen had been mainly due to the collection of blood within it. The rupture was found in the left Fallopian tube, which was the seat of an early pregnancy near, but not quite close to, the uterus. The tube was small and atrophic. This with its corresponding ovary was removed. The patient made a good recovery.

Mrs. B, aged thirty years, having had one child, nine years previously, and one miscarriage five years before, had been menstruating regularly since the date of the miscarriage until some two months before I saw her. The last period had been delayed for one week but on its appearance was normal in its course. This again had been followed by amenorrhœa of five weeks' standing. On the evening of July 13th, 1895, she had some slight abdominal pain, for which she herself attended the consulting rooms of Dr. H. Shillito. I met him in consultation on the 15th and found general abdominal distension, with vomiting and faintness, marked pallor of the face and lips, and a running pulse (150). On examination a doubtful boggy fulness was felt in the pouch of Douglas. The diagnosis was made of tubal rupture. Abdominal section about midnight on the 15th disclosed an early pregnancy of the left tube with linear rupture near the uterus. The appendages were removed. The patient recovered.

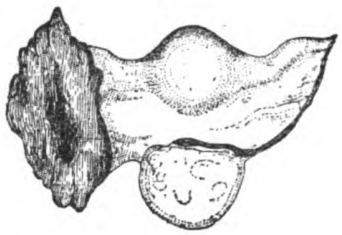
In both of these cases the patients were almost moribund at the time of operation. In the last case the illness was then of 48 hours' standing, in the other of about 16 hours' only. In neither case was there any evidence of previous bleeding or any symptom before the sudden illness which I have reported.

In these cases of early rupture it is important to notice that but little or no change takes place in the affected tube except at the exact seat of pregnancy and rupture. This may be found at any part in the course of the tube except at the fimbriated extremity, but its favourite situation is near to the uterus on the tubal side of the uterine ostium. There is no closure of the abdominal end of the tube and no swelling of the tube except at the site of pregnancy. On the contrary, the condition found on operation appears to show that the tube is often ill-developed and small, the muscular coat defective and the uterine ostium contracted. The remains of the tube enclosing the pregnancy are thin and papery and there is no evidence whatever of the slightest attempt at any compensatory growth surrounding the affected area. I have operated on four cases of this class and in all of these the conditions were essentially as here described. In one case the atrophic state of the tube was very marked and can be still recognised on simple inspection of the specimen. The Fallopian tube in this instance presents the very unusual features of double rupture, having been twice the seat of an extra-uterine pregnancy. The first tubal pregnancy occurred in 1889. This resulted in rupture with limited hæmorrhage at the sixth week. Peritonitis followed and a hæmatocele formed which was slowly absorbed after six or seven weeks' rest in bed, the whole

FIG. 6.

of the illness being passed under my own personal observation. Two years later (in 1891) another pregnancy took place in the same tube, the history of which has already been recorded. On examination of the specimen then removed (Fig. 6) the original rupture of 1889 may be clearly seen surrounded by the remains of old adhesions, while the more recent rupture is marked by protruding blood-clot and membrane near the uterine end of the tube. This end of the tube is notably small and thin and the slender sheath of muscle tissue in it is almost microscopic. At the site of the pregnancy, just beyond this, no muscular coat can be seen at all and the black clot of the ruptured pregnancy is everywhere visible beneath the thin peritoneal investment which marks all that remains of the dilated tube in this situation. The atrophic state of the tube, so well displayed in this specimen, is probably the important factor both in the causation of the disease and in its termination by early rupture. The Fallopian tube has not had the muscular strength necessary to extrude the fructified ovum into the cavity of the uterus, arrest near the uterine end of the tube has been followed by fixation and growth of the ovum, and for want of any substance in the enveloping tube its necessary expansion has been almost immediately followed by rupture.

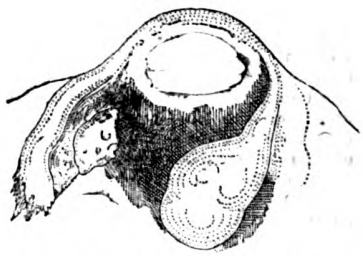
Although rarely present, perhaps, in so marked a degree as in this specimen, it is highly probable that some amount of non-development or atrophy of the tube is responsible for nearly all the cases of early rupture. The condition may arise as the sequel of a previous pregnancy, some excess of involution affecting both uterus and tubes. In the rare case I have described it may have followed the previous tubal pregnancy or it may have existed before this date (I have not the tube of the opposite side with which to compare it). There can be no doubt that the condition is a real one and that its recognition and consideration will do much at present—and still more, I believe, in the future—to explain the phenomena attending a most important group of ectopic pregnancies. Other specimens and histories extremely similar to those I have described may be found in our more important museums and these abundantly show the frequent association of early rupture and diffuse hæmorrhage with pregnancy of the uterine end of an atrophic or ill-developed tube, the course of which is unmarked by any alteration or adhesions except at the site of pregnancy and the fimbriated end of which is open. As examples I may cite Specimen No. 4695 of the Museum of the Royal College of Surgeons of England, presented by Dr. Walter Lowe, "From a woman, aged thirty-three, who, when not aware of being pregnant, was seized with severe abdominal pain and collapse during defecation. She died within nine hours." No. 2517[62] from Guy's Hospital Museum shows the rupture of an extra-uterine fœtation of the sixth week. The pregnancy is close to the uterus, the coverings are very thin, and the fimbriated end of the tube is unaltered. No. 2517[65] is a similar specimen of early rupture. The coverings are very thin. The tube is otherwise unaltered. The rupture is near the uterus. Death occurred in ten hours. Specimen No. 90 in Mason College Museum is a very good example. The tube is more like a folded piece of paper than an organ containing muscle structure. No. 79 is probably an example in which both of the Fallopian tubes were atrophic. The histories of these specimens are, however, not preserved. Another good specimen is No. 2484 in St. Thomas's Hospital Museum. In this specimen the atrophy of the tubes on both sides is very evident, while the left tube near its uterine end is the seat of an early pregnancy which has ruptured into the abdominal cavity. The patient died from "fatal peritonitis."



Sometimes the condition is found at the very first pregnancy and then the want of development of the tube is probably congenital. Mrs. C, aged thirty years, had been married for seven months. Menstruation had been perfectly regular, the last period occurring four weeks before the date of consultation. Some irregular hæmorrhage had taken place from the vagina for eight days. When seen by me the patient was blanched from hæmorrhage, the abdomen was distended, and on examination the uterus was felt to be surrounded by a soft mass (of blood-clot) filling the pouch of Douglas. I opened the abdomen the same evening and found it full of fluid blood and blood-clot. The left Fallopian tube was ruptured close to its uterine end and was removed. The covering of the pregnancy was everywhere thin and semi-transparent and appeared to consist of peritoneal coat only. The patient died during the third week from some slow septic (?) process attended with but little or no rise of temperature and exceedingly difficult to understand. The operation was performed in a small house in the country and the conditions may have been unsuitable and insanitary.

A specimen with a very similar history is to be seen in the Museum of the Middlesex Hospital (No. 2050). In this case

the rupture is near the fimbriated end of the tube, but the tube is small and ill-developed. The rupture is stated to have occurred at the first pregnancy and only one menstrual period had been passed. It is interesting to notice that a paper by Professor Dührssen (in a recent number of the *Archiv für Gynäkologie* which was published after this section had been written) confirms to a very large extent the view I have advanced regarding the association of tubal pregnancy with atrophy of the tube. So far as I have been able to follow him Professor Dührssen has not noticed any special relation between atrophy and earliest rupture of the tube, such as I have described, but his general conclusions are precisely similar and are supported by the evidence of microscopical sections as well as by that derived from ordinary specimens.



2. *The "tubal mole."*—In a large number of cases pregnancy within the Fallopian tube results in the formation of a "tubal mole" at a very early stage of gestation. Hæmorrhage occurs (as Mr. Bland Sutton has explained) into the "subchorionic chamber" from the circulation of the embryo. In other words, blood is poured out into the space between the amnion and chorion, the embryo is injured or destroyed, and a mole of pregnancy results in the same way as it does when a similar accident occurs within the uterus. In a very few cases (one is reported by Mr. Sutton) the mole is extruded from the Fallopian tube into the abdominal cavity, forming a true "tubal abortion." In by far the greater number of cases, however, the "mole" remains strongly attached at one part to the inner surface of the tube. This point of attachment marks the site of what would afterwards have been the placenta if the pregnancy had continued to develop, and some of the specimens of tubal mole afford good opportunities for examination into its usual extent and consistency. The union of tube and ovum is remarkably firm in this situation, but the extent of the union is limited. The mole clings to the tube like a pedunculated polypus, all the circumference of the ovum except at the point of attachment being absolutely free. Until the placental site is differentiated from the rest of the chorion and attachment is made the fructified ovum is probably freely moveable; as soon as the attachment is formed it steadily increases in strength and if the pregnancy goes on it is very probable that *no subsequent change will altogether separate the relations of ovum and tube.* This is not only of importance in the later stages of extra-uterine gestation, as we shall see hereafter, but even at this stage the attachment of the "mole" is a source of serious trouble. For although the pregnancy becomes abortive it does not then become innocuous or quiescent. On the contrary, the blighted ovum remains hanging from the inner surface of the tube. It is a source of continuous irritation and hyperæmia in the maternal tissues to which it clings, and is the cause of repeated and dangerous bleedings from the Fallopian tube into the abdominal cavity. It is true that an attempt is made towards closure of the abdominal ostium of the tube. In acute gonorrhœal salpingitis, as is well known, this closure is usually complete, but in the sub-inflammatory processes occasioned by "tubal mole" the salpingitis is much less marked and the closure is incomplete. The tube becomes thickened and more vascular, and at the fimbriated end the ring where peritoneum ceases and mucous membrane begins is subject to a slow contraction which tends to partially confine the blood which is effused within the

FIG. 7.

lumen of the tube. The consequent enlargement and dilatation of the tube on the uterine side of this ring of contraction withdraws some of the fimbriæ back within the tube, but the process rarely proceeds further than this in "tubal mole." The abdominal ostium still remains patent though contracted and is still marked by a small rosette of fimbriæ on its abdominal aspect. The external or peritoneal aspect of the tube is marked by a globular swelling corresponding to the situation of the "mole." This in the removed specimen (Fig. 7) is very characteristic. Apart from this the changes which occur in the tube—in size, shape, position, and mobility—are very much the same as in other cases of tubal enlargement. As a rule, and especially when the pregnancy is situated near the fimbriated end, the enlarged and heavier portion of the tube containing the "mole" falls directly behind the uterus, rotating somewhat as it does so, and therefore dragging over it and its corresponding ovary the free portion of the broad ligament to which it is attached (mesosalpinx). This takes place very early in the course of the complaint, before any bleeding occurs or inflammatory adhesions form. Almost immediately afterwards, however, as we have already seen, bleeding begins both into the tube and from the abdominal ostium; inflammation follows and the tube becomes increasingly distended and adherent. The tumour, which was originally small, strictly posterior in position, moderately mobile and well defined, slowly extends to one side or the other, and instead of the small, well-defined tumour, limited to the site of pregnancy, we have a complex mass consisting of tube, ovary, broad ligament, and blood-clot, which tends to fill one side of the pelvis and finally displaces the uterus to the opposite side, pushing the opposite tube and ovary close up against the pelvic wall. The uterus itself is enlarged, a decidua has formed within it, and its consequent increase in bulk tends to accentuate the displacement. An attempt is made in the following sequence of illustrations to roughly depict the changes liable to occur in the tumour occasioned by a "tubal mole." In all the uterus and its appendages are sketched as seen from behind. In the first (Fig. 8) we see

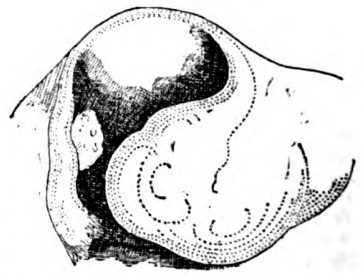


FIG. 8.

the little tumour of the tubal pregnancy before any hæmorrhage has taken place. It is moveable, hanging freely in the tube, and tends to fall or settle (by its own weight) directly behind the uterus. At this stage it either has no effect at all on the position of the uterus or tends to drag it backwards and also to displace it slightly towards the same side. In some cases the backward displacement of the uterus is very marked, amounting to decided retroflexion. In others (as in the illustration) the retroflexion of the uterus is less marked. It is quite exceptional, however, for the uterus to be anteflexed as it is so often in the early stage of normal pregnancy. The tumour of the pregnancy takes the most dependent position and the fimbriated end of the tube is tilted up toward the ovary anterior to this and therefore out of sight.

In the next figure (Fig. 9) we see the tube generally distended with blood. The space beneath the mesosalpinx is

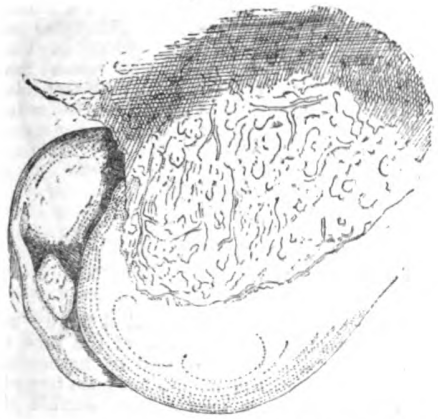

FIG 9.

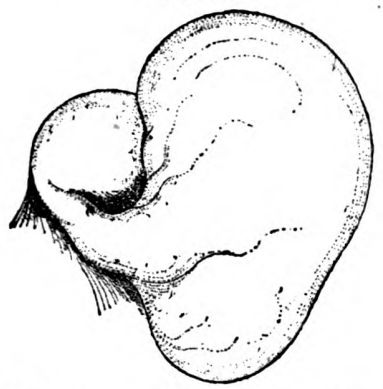
also filled with blood-clot and blood is escaping into the pouch of Douglas. The complex tumour formed by the



pregnancy—consisting now of the "mole" of pregnancy, distended tube, adherent ovary, and hæmatocele covered more or less by the mesosalpinx—has become fixed by adhesions; it is extending outwards and upwards. It is beginning to fill the right side of the pelvis and as it does so it pushes the uterus and opposite appendages decidedly to the left. In the next illustration (Fig. 10), which has been less easy to

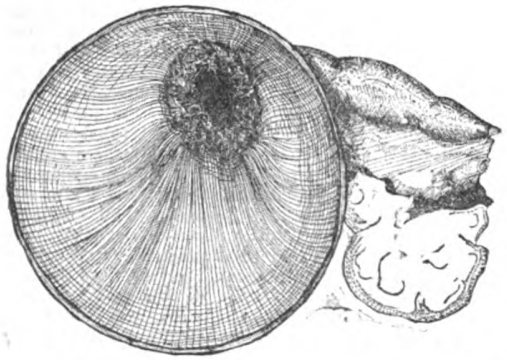
FIG. 10.

draw and therefore may be less easy to understand, we see that the uterus has been pushed quite over to the left by the growing mass, so that it must now be close against the pelvic wall and rectum. Considerable hæmorrhage has taken place beyond and above the limits of the tube and the tumour formed by this has been roofed in by adhering omentum. The tumour almost fills the pelvis and is extending up into the abdomen above Poupart's ligament. If it continues to grow the uterus will be almost buried beneath it. This tumour (of pregnancy and blood-clot) is usually on the same side of the body as the tube containing the pregnancy. But it is not always so. I have known one case[5] (No. 22) in which, although the general configuration of the tumour was very much as I have been describing, the bulk of the tumour was on the opposite side of the body to that of the tube containing the pregnancy. In this illustration (Fig. 11)—

FIG. 11.

the last of the sequence—taken from the case I have mentioned, we see the left Fallopian tube crossing the back of the uterus from left to right, lengthened by the growth of the pregnancy and finally terminating in a large right-sided hæmatocele which occupies the right iliac fossa as well as the pouch of Douglas. In other words, we have a left tubal pregnancy causing a right iliac hæmatocele. The uterus in this case suffers rather less lateral displacement than in the previous case, but it is strongly displaced forwards, being pressed against the pubes by the tumour behind it. Sometimes, again, the tumour is originally lateral in position and remains so throughout, the pouch of Douglas being comparatively empty. The tumour is then closely applied to the upper part of the body of the uterus, moves with it, and may easily be taken for some enlargement of the fundus itself.

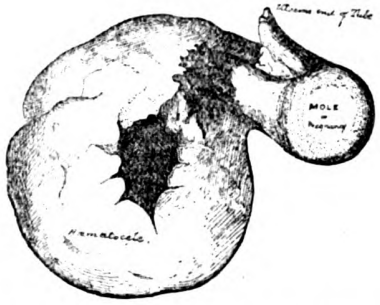
Intra-peritoneal hæmatocele, which has been already incidentally referred to and partially described, is a pathological product concerning which much has been learnt during recent years. In women it is almost always caused by tubal pregnancy, sometimes by rupture of the tube and sometimes by bleeding from the fimbriated end of the tube without rupture. The latter is the more common cause of intra-peritoneal hæmatocele, and this bleeding from the unruptured tube is usually set up by the presence of a "hæmorrhagic mole" within it. Cases of "tubal mole" with intra-peritoneal bleeding from the open abdominal ostium probably outnumber the cases of tubal pregnancy with rupture of the tube; the hæmorrhage though almost continuous or frequently repeated is moderate in amount, and a well-defined hæmatocele is the invariable sequel. On the other hand, cases of ruptured tubal pregnancy only sometimes give rise to a definite hæmatocele. In fully half the number of cases the resulting hæmorrhage is "diffuse"; no time or opportunity is afforded for the formation of a definite blood-tumour, but the hæmorrhage continues until stopped by operation or death. In the remaining cases where a hæmatocele follows the latter is often very unstable and subject to sudden and violent alterations from fresh bleeding, so that the tumour may be said to occupy a position midway between intra-peritoneal hæmatocele and diffuse hæmorrhage.



Occasional exceptions to the rule thus formulated are known. For instance, I have met with a case of "tubal mole" (Case 14) in which the hæmorrhage from the unruptured tube, although it resulted in an intra-peritoneal hæmatocele, was, after recurrence and rupture of the hæmatocele, fully as copious and dangerous as that which I have usually found after later rupture of the tube; and, again, I have known at least one case of rupture of the tube (Case 36) resulting in a definite and localised hæmatocele in which the bleeding was very moderate and the tumour resulting from it quite small in size. These exceptional cases, however, do not interfere with the general truth of the statement that rupture of the tube is specially liable to be followed by diffuse bleeding, while hæmorrhage from an unruptured tube containing a "mole" of pregnancy is essentially the most common cause of intra-peritoneal hæmatocele. My own statistics on this point are as follows: Out of 21 cases of intra-peritoneal hæmatocele due to tubal pregnancy (in which the condition of the tube was carefully noted) I find that 14 were due to hæmorrhage from the unruptured tube, while 7 were associated with rupture of the tube. Dr. Cullingworth's figures are still more striking. He states: "Of 25 cases of pelvic hæmatocele in which an opportunity occurred of verifying by actual inspection the source of the bleeding 23 were instances of hæmorrhage from the open abdominal ostium of a pregnant Fallopian tube and only 1 was due to rupture."

The formation of the hæmatocele is a process full of interest. Much of this has been already described when treating of the tumour formed by the "tubal mole." But when the bleeding has reached beyond the limits of the tube and ovary and uterus, when it invades the abdomen from the pelvis, how is it limited and what is the process by which a more or less amorphous mass of blood-clot becomes welded or shaped into a definite tumour? It must be remembered that the living abdomen is always full. Consequently when any blood is effused into the pelvis it is in contact with the pelvic viscera—at first with the tube, the ovary, and the turned-in fold of the broad ligament; later, omentum and intestine come into contact with the growing blood-clot, local peritonitis is set up by the hæmorrhage, the pelvic and abdominal viscera become adherent to the surface of the blood-clot, and the latter is bounded everywhere by "peripheral adhesions" to surrounding organs. The intra-peritoneal hæmatocele is temporarily formed. But another process is going on beside this. The outer layer of the blood-clot consolidates into a more or less perfect sac, and in addition to the adhesions the blood becomes encapsulated by a limiting layer or outer coat derived from its own substance or tissue. Sometimes the hæmorrhage within this capsule ceases altogether. In process of time the adherent viscera become detached and we may find a perfect sac remaining closely fitting round the abdominal mouth of the Fallopian tube, blood being found within it. This, which I have described elsewhere, is known as encapsulated

[5] A list of 37 cases (36 recoveries and 1 death) will be given with Lecture III.



hæmatocele, and examples of this condition are well seen in the specimens removed from Cases 7 and 8. (Fig. 12.) In the specimen from No. 7 the sac of the hæmatocele is altogether independent of the ovary and tube, though

FIG. 12.

the mouth of it was closely applied around the fimbriated end of the tube. (Fig. 13.) In the specimen from No. 8 the ovary is incorporated with the wall of the hæmatocele, while a "mole" of pregnancy is visibly distending the

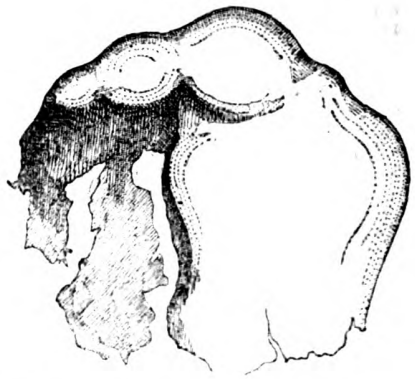


FIG. 13.

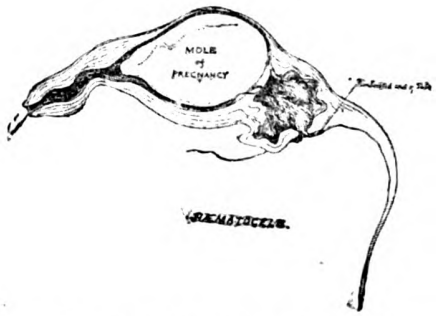
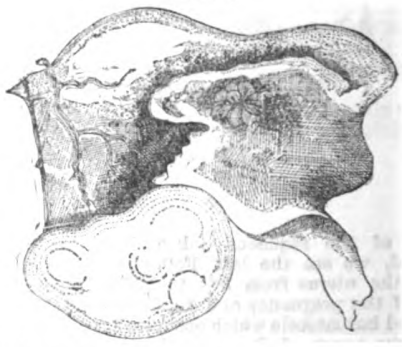
unruptured tube. In the figure the tube has been withdrawn from the inside of the sac in order to show that it is uninjured and intact, but before the separation of the tube from the sac the latter in this case formed a marked tubo-ovarian tumour which evidently might have given rise to the (unfounded) suspicion of an ovarian pregnancy. But it is only rarely that the hæmorrhage ceases on the immediate formation of the hæmatocele. In nearly all cases of tubal pregnancy with hæmatocele the bleeding is recurrent. The source of the bleeding is the tube and this is necessarily now in the centre of the hæmatocele. The outer covering of the latter is stretched and distended; somewhere it "gives" to the strain, fresh blood and blood-clot are forced through the rent or bulge through the weakened capsule into the abdomen, fresh local peritonitis occurs, fresh adhesions form, the rent is patched up, and the hæmatocele (greatly increased in size) again goes on.



In operating on a hæmatocele which has been formed in this way by several recurrent bleedings from the fimbriated end of an unruptured tube, what sort of a specimen do we remove? The recent blood and blood-clot at the site of the last abdominal bleeding—the weakest part of the hæmatocele—are involuntarily broken down by the hand on touching the tumour; this and the central part or contents of the hæmatocele are washed or scooped away, parts of the outer wall are broken off and left adhering to intestine or omentum, and when the Fallopian tube together with the remainder of the sac is ligatured and removed we find the outer shell of the hæmatocele forming a curious ragged extension of the tube, and if we view the tattered remnants of the capsule from within we may usually observe some fimbriæ of the tube at one point on the inner wall. This marks the aperture of entrance from the tube into the hæmatocele. The following sketches of specimens removed from Cases 14, 12, and 9 show this very plainly (Fig. 14). In Fig. 14 we see a specimen which looks at first sight like a tubal pregnancy which has ruptured into the broad ligment so extensive are the remnants of the capsule continuous with the tube. On careful section, however, we see

FIG. 14.



that it is unruptured (Fig. 15), that a large "mole' of pregnancy occupies the middle portion of the tube, that the outer end of the tube has been dilated by hæmorrhage, and that the greater part of the tumour has been formed by the capsule of the hæmatocele, on the inner surface of which

FIG. 15.

the fimbriæ of the outer end of the tube abruptly terminate. Similarly in Figs. 16 and 17, although the remains of the hæmatocele capsule are much less extensive, we may recognise in each the unruptured tube (complete from uterine end to fimbriæ), the "mole" distending one portion of the

FIG. 16.

tube and the rosette of fimbriæ opening on the inner wall of the hæmatocele capsule.

The following case, to which the specimen depicted in the last illustration belongs, may be taken as fairly typical of the history associated with such "tubal moles" and blood tumours as I have been describing.

Mrs. D., aged thirty-nine years, had been married for seventeen years. She had had five children, the youngest of whom was eleven years of age. Her last normal

menstrual period was on June 3rd, 1892. She had had irregular internal hæmorrhage since July 10th. There was no clear history of the passage of any definite membrane but it was quite possible that shreds of membrane had passed with the discharge. She had been perfectly well until quite recently and even now complained of nothing but the menstrual irregularity and continued loss. This history was taken on her first visit to the hospital on Aug. 26th. On examination I found that the uterus was retroflexed and that

FIG. 17.

a small mass having all the characters of a tubal tumour was to be felt behind and to the right of the retroflexed uterus. The diagnosis was made of early extra-uterine pregnancy, but I had no vacant bed and the patient was allowed to return to her home. On Sept. 2nd she began to suffer severe abdominal pain and this date probably marks the beginning of intra-peritoneal hæmorrhage. On Sept. 13th she was admitted into hospital having been confined to her bed for several days with recurrent abdominal pain and sickness. On admission she was seen to be decidedly anæmic, her abdomen was generally distended and very tender, she lay in bed with her legs drawn up, her countenance denoted anxiety and suffering, and on examination, instead of the definite tubal tumour originally felt the whole of the pouch of Douglas was recognised as filled by a mass the upper limit of which it was impossible to define on account of the abdominal distension and tenderness. To the diagnosis of tubal pregnancy the further diagnosis was added of "intra-peritoneal hæmorrhage." On Sept. 15th I operated, removing the specimen which has already been briefly described. There was some dark fluid blood free in the pelvis, the result of a recent rupture of the hæmatocele. The main tumour filling the pouch of Douglas consisted of this hæmatocele which had formed around the fimbriated end of the right Fallopian tube. Within the tube a "mole" of pregnancy was found. The patient made a good recovery and was discharged on Oct. 8th.

Sometimes the whole of the pouch of Douglas is occupied by the hæmatocele. When this is the case there is, as a rule, no prominent tumour in the abdomen, but an irregular thickening stretching across the lower part of the abdomen above the pubes which marks the upper limit of the blood effusion. The prominence and distension of the hæmatocele caused either directly by the hæmorrhage or secondarily by inflammatory effusion below its upper limit is entirely expended on the pouch of Douglas. This enlarges in every direction and encroaches on the vagina and rectum until the typical tumour is formed which is characteristic of full distension of the pouch when its upper connexion with the general peritoneal cavity is temporarily occluded. Some writers describe this as the common or usual result of intra-peritoneal bleeding. In my own experience it is quite exceptional. Whenever it does occur the difference of tension between the distended pouch of Douglas and the upper abdomen proclaims the fact that the lowest part of the peritoneum is entirely shut off by adhesions from the rest of the cavity and because of this (as we shall see) the condition can be treated as a purely local affection.

3. *Later rupture of the pregnant tube.*—This may take place at any time from the first month onward, but is most common from the second to the fourth month. If the pregnancy is situated in the middle or outer portion of the tube, and especially if in its growth it opens up to some extent the two layers of the mesosalpinx, the pregnancy may continue to develop for some weeks before rupture or extrusion occurs. When rupture does take place, although the accident may be fatal (and usually is so without operation), the hæmorrhage is probably never so directly and immediately fatal ("fatal without warning"), as in the cases of very early rupture when the pregnancy is situated at the uterine end of the tube. It is even possible for hæmorrhage to be altogether absent. The reason for this variable amount of hæmorrhage is to be mainly sought for in the involvement or escape of the placental attachment. The tube, subject to slowly increasing pressure from within, becomes stretched and thin. As it enlarges and opens up the layers of the mesosalpinx space is gained in which a pregnancy may develop for some weeks without material difficulty. This space is further protected by the bony pelvis on the side where the pregnancy is situated and on the opposite side the displaced uterus forms a strong support or boundary. But the time comes, and usually about the third month, when this space is altogether insufficient for the growing tumour. Then either the peritoneum must be still further displaced and the pregnancy must burrow downwards into the cellular tissue beneath it (this belongs to tubo-ligamentary pregnancy and will be considered later) or the covering of the pregnancy gets thinner and thinner and the pregnancy moves upwards until in some places there is probably nothing but the one layer of peritoneum between it and the abdominal cavity. Then with further growth not only is rupture inevitable but some extrusion of the pregnancy into the abdomen—either partial or complete—is a necessary consequence also. For the present this alone will engage our attention. If the placenta be exposed, separated, or torn the bleeding will be severe; if, on the contrary, the placenta is not involved by the rupture any hæmorrhage will come from the separated tube alone, and this may be moderate, infinitesimal, or wanting. Even if placental the bleeding is only rarely directly and immediately fatal. "As the blood-pressure falls the hæmorrhage ceases—at all events for a time—and a more or less well-marked attack of local peritonitis immediately follows. This peritonitis is neither so violent and dangerous nor so protective (by the formation of firm adhesions) as is the peritonitis set up by suppurative inflammation, but it is sufficient to form a kind of roof or cap of adhering omentum and intestine which covers and confines the hæmorrhage and blood-clot. In this way a distinct but unstable intra-peritoneal hæmatocele is formed. I call it unstable because it is always subject to change. Fresh hæmorrhages occur sooner or later, owing to the increasing detachment and protrusion of the placenta which so frequently follows the rupture, or the pregnancy may continue to grow. In either case the hæmatocele increases in size, its upper limit becomes convex and tense from the augmented contents, and every few days or every day some fresh strain is placed on the boundary of the hæmatocele. This, which was never marked by any solidity or strength, finally gives way and a fresh invasion of the general peritoneal cavity takes place. Under these circumstances diffuse hæmorrhage into the peritoneum may occur and be as marked as in the case of acute bleeding from early rupture, but is more frequently followed by another arrest and further repair. Whether this happens or not, however, it is not now so much the rupture of the tube which is the seat of danger as the separation of the placenta and the rupture of the hæmatocele."

From this description, which (in the main) I quote from an article on "Intra-peritoneal Hæmatocele," written in 1895, it will be evident that the hæmatocele caused by later rupture of the tube—when fully formed—is essentially similar, save in extent and severity, to that which I have already described as occasioned by "tubal mole." There are, however, some points of difference which almost necessitate the separate consideration which I have given to the hæmatocele of "tubal mole" and to that of later tubal pregnancy with rupture. The hæmorrhage in "tubal mole" is of quite a different character from that which occurs in late rupture of the tube. In "tubal mole" it is a more or less continuous blood-drip from the fimbriated end of the tube, varied perhaps by an occasional little gush of freer bleeding at irregular intervals. In later rupture of the tube the hæmorrhage is sudden and relatively copious, arising, as we have seen, either directly from the tear in the tube or from separation of the placenta or from both combined. In "tubal mole," owing to the slower formation of the blood tumour, the outer layer of blood

has time to consolidate and some measure of true encapsulation, however imperfect, is usually met with. In later rupture of the tube, on the contrary, any encapsulation is quite exceptional, and the hæmatocele is limited only by the inflammatory adhesions caused by the peritonitis which follows the hæmorrhage. Finally, the whole condition in later rupture of the tube is more "acute." The hæmatocele is larger at its onset and rapidly increases in size. It may often be visibly watched enlarging and distending as fresh bleeding takes place beneath the thin limiting adhesions and it is then accompanied by signs and symptoms proportionate to the severity of the condition.

Mrs. E, aged thirty-one years, married eleven years, had had one child ten years ago (in 1885). From this time she had menstruated regularly until Oct. 12th, 1894, this being the date of the last normal period. Irregular hæmorrhage followed and continued from October to Jan. 27th, 1895 (the date of operation). During the latter part of this time she was the subject of increasing abdominal pain, mainly referred to the right side and accompanied by distension, vomiting, faintness and constipation. Some jaundice and albuminuria were also present; the temperature was slightly raised, fluctuating from 99° to 101·3° F. In spite of the general abdominal distension a large mass was to be felt on the right side of the abdomen, reaching from the groin to the umbilicus and having in this situation a convex free border and a more or less globular elevation. The abdomen was very tender to the touch. The mass had been felt by the patient and observed by her medical attendant as rapidly increasing in size from a small lump above the groin to its present dimensions, during the week or ten days before my visit. On vaginal examination a large firm tumour was felt in the pouch of Douglas behind the uterus, and this appeared to be continuous with the abdominal tumour. The diagnosis having been made of intra-peritoneal hæmatocele due to a ruptured tubal pregnancy, the abdomen was immediately opened. This contained a little coloured serum but was free from any diffuse hæmorrhage. The mass on the right side, black in colour, was confined by thin adhesions and the convex border was formed by small intestine, transverse colon, and omentum matted together over the surface of the hæmatocele. An opening was made below this and the child (a fœtus of some two months' growth) together with the placenta were removed from the centre of the blood and blood-clot in which they were lying. The placenta had already become almost entirely detached from the tube by hæmorrhage and the slightest traction was sufficient to complete the separation. The tubal sac which had contained the placenta and was the seat of an extensive rupture was found to be slightly adherent beneath the blood-clot. It was separated from its posterior adhesions, unrolled from the floor of the pelvis, ligatured, and removed. The patient made a good recovery.

Mrs. F, aged thirty-eight years, menstruated regularly from the birth of her last child (twelve years previously) until November, 1887. In December, 1887, and in January, 1888, she had occasional loss of blood but no regular period and from November she suffered from gradually increasing pain in the right side. Early in February she noticed a "lump" in this situation which rapidly enlarged with corresponding increase of pain, and during the latter part of this month she had been unable to sleep on account of pain. She also suffered from dysuria and frequency of micturition. When seen (on March 4th, 1888), a tender, tense, elastic or semi-fluctuant tumour was found on the right side of the abdomen, extending from the pelvis to within a short distance of the umbilicus. The uterus was fixed and pushed to the left by the tumour, and the medical man in attendance reported that the tumour was "rapidly enlarging." I opened the abdomen on March 7th. The tumour, black in colour, was formed by a mass of blood and blood-clot filling the pelvis and the right inguinal region, and closed in or separated from the general peritoneal cavity above by adherent omentum. On loosening this a fœtus of four months' growth was found in the middle of the blood-clot, while the placenta was still attached to the interior of the left Fallopian tube, in which the pregnancy had started. The tube had become widely opened out at its fimbriated extremity and this was the only rupture found, but there was some marginal separation of the placenta and this separation was most likely the source of the hæmorrhage. The tube and the fœtus were removed in the usual way and the patient made a good recovery. During the removal of the pregnancy the amniotic sac was torn and only a portion of it can now be seen. (Fig. 18.) Before operation it was in all probability intact

FIG. 18

and completely covered the fœtus. If I restore this amniotic sac, replacing the outline of it around the fœtus and cord, and if, for purposes of argument or explanation, it be conceded that the bleeding might have ceased and the portion of the placenta separated from the tube have recovered good attachment and blood-supply, we shall reproduce the exact conditions under which a child may continue to grow within the abdomen of the mother. In other words, the tubal pregnancy may be recognised in this specimen as transitional; the tubal pregnancy is already becoming "abdominal" or ventral, and had the hæmorrhage at extrusion been less severe or wanting it is quite possible that such a pregnancy might have gone to term, the child developing within the abdomen of the mother.

A CASE OF GENU RECURVATUM.

BY A. MARMADUKE SHEILD, M.B., B.C. CANTAB, F.R.C.S. ENG.,

ASSISTANT SURGEON TO, AND LECTURER ON PRACTICAL SURGERY AT, ST. GEORGE'S HOSPITAL.

AN infant, aged about eight weeks, came under my care in April, 1898, with the extraordinary deformity depicted in the accompanying illustration (Fig. 1). The legs were hyper-extended on the thighs at an obtuse angle and a

FIG. 1.

Position of the limbs in a case of genu recurvatum.

transverse furrow extended across the front of the joint as though the popliteal flexure was in front. The toes pointed towards the abdomen. Considerable resistance was offered to any attempt to straighten the limbs, which were otherwise

well developed. The hip-joints seemed to be normal, though as the infant had, of course, not walked it was difficult to estimate whether the acetabulum was well-formed. The child was born by a head presentation. The condition of the limbs was noticed at birth. It was a fifth child and all the others were well formed.

The limbs were straightened and somewhat flexed under chloroform. The child took the anæsthetic badly and doubts were expressed as to the possibility of congenital cardiac imperfection. Posterior splints were applied. About 10 days after the child, who looked puny and weak, refused nourishment, became feverish and died. The cause of death was not clear and examination of one knee-joint only was performed. The right was selected as being the more markedly deformed. Some extravasations of blood were seen in the soft parts round the joint. On dissection the following remarkable conditions were found. The arrangement of the soft parts in the popliteal space was normal, excepting that the hamstring muscles seemed stretched over the prominent condyles of the femur. The posterior ligament was intact, but somewhat elongated and greatly stretched. The tendon of the quadriceps terminated as usual in the ligamentum patellæ, which had its usual attachment. The position of the bones brought the under surface of the patella to the front of the femur above the inter-condyloid notch and here a very important appearance was noted. The under surface of the patella was not articular and the tough fibrous aponeurosis was intimately adherent to the front of the femur above the inter-condyloid notch so that it could only be dissected away with difficulty. There seemed to be no undue contraction of the quadriceps. The crucial ligaments were normal in position, but they resisted flexion and seemed to be too short. The capsule and lateral ligaments were tough and contracted and the bones could not be brought into position until these structures were freely divided. The position of the bones was very interesting. The articular surface of the tibia lay on the front articular surface of the femur in the position ordinarily occupied by the patella, and the condyles of the femur, covered by the stretched posterior ligaments, projected markedly backwards into the popliteal space. The process

FIG. 2.

Genu recurvatum. The patella can be seen as a nodule in the substance of the quadriceps extensor. The attachment of the latter to the femur are shown and also the stretched posterior ligament. The tibula articulates with the front of the articular surface of the femur.

straightening had therefore not really affected the dition of the articular positions, but was due to a bending the tibia at its epiphyseal junction. The accompany- ; illustration (Fig. 2), executed by Mr. Mummery, ll shows this dislocation of the tibia forwards and position of the patella above the inter-condyloid notch. Owing to the position of the patella above the inter-condyloid notch it could not be felt during life and was taken to be absent. There was no marked peculiarity in the joint-surfaces of the tibia and femur, except that the articular surface of the latter seemed to extend further forwards than usual.

This deformity is a rare one and due to uterine malposition, the legs, instead of being flexed on the thighs, are extended, with the feet pressing against the neck or portions of the face. Injury to the mother during gestation has been observed in some of the cases recorded and Mr. Shattock has suggested that intra-uterine tetany of the fœtus may be a possible cause. One of the few cases of dissection of this condition is recorded at length by Mr. Shattock.[1] This writer gives a bibliographical list and refers to two cases under the care of Mr. Bernard Pitts. The history of injury to the mother is marked in one of these. In the dissection of a full-term fœtus conducted by Mr. Shattock the patella was found above the inter-condyloid notch, as in my case, and the same contracted condition was noticed in the capsule and lateral ligaments. The under surface of the patella was articular, not separated from the joint, as in this case, and the lower end of the femur viewed from the front shows two facets upon which the articular surface of the tibia rested. The child was born by a head presentation, and Mr. Shattock considers Mr. Adams to have been in error in stating that these cases were breech presentations. The pressure of the sole of the foot against the face had caused absence of the chin in the case described by Mr. Shattock. In other cases examined by the same pathologist essentially the same features were found. The hip-joints admitted of only limited extension. The knees were over-extended and it was only after directing the whole of the capsule in front of the lateral ligaments that the joint could be flexed.

Mr. Edmund Owen has published a typical case of genu recurvatum.[2] The child was aged three years and nine months and the mother had suffered from typhus fever before the confinement and during delirium had imagined herself to be a fish. The child sat, with the back of each foot resting upon the collar-bone. There was a transverse furrow in front of the knees, above which the patella could be made out. The patient was treated by a transverse incision of the quadriceps and the result was excellent. It is not quite clear from the account whether the fibrous capsule of the joint was also divided, but I should think that this is probable. Whether good flexion of the limbs alternately resulted in this case I am not able to state.

On March 18th of this year I saw a private case of this affection in a boy, aged eight years. His trunk and upper extremities were well developed and he was very intelligent. There was deformity and osseous thickening about the elbows and the metacarpo-phalangeal joints of the thumbs. The inner condyle of the humerus seemed markedly enlarged and the deformity about the thumbs seemed to affect the head of the metacarpal bone. Movements and function of the upper extremities were excellent. There was marked genu recurvatum on both sides, with extreme genu valgum, the inner condyle being markedly enlarged on both sides. The boy could walk remarkably well considering all things, but principally upon his heels. There was great lordosis. The right hip joint was displaced and the head of the femur slipped in and out in a characteristic manner. On the left side apparently no displacement existed. The limbs could be straightened by manipulation but not flexed. There were signs that daily massage and flexion would result in improvement. This patient had been seen since infancy by surgeons specially practising orthopædic surgery, but they had advised no active treatment.

It seems, then, that so far as our knowledge of this curious and rare deformity goes, it amounts to this. The cause is intra-uterine malposition, perhaps excited by an injury during pregnancy. The shortened ligaments in obedience to the law of arrest of growth from non-performance of function do not develop and hence the apparently contracted condition of the capsule. Other deformities may co-exist, as dislocation of the hip, or absence of the chin from pressure, or cardiac imperfections.

Considering the serious impediment to motion early treatment should be adopted. This consists in gradual flexion and splinting of the limbs. Should the tissues resist these

[1] Transactions of the Pathological Society of London, vol. xlii.
[2] Transactions of the Medica Society of London, vol. xiv.

minor measures I would advise waiting until the child be a year or two old and then dividing the resisting capsule and ligaments by an open operation under strict asepsis. The muscles round the joint seem to have little to do with the deformity and it is to the fibrous capsule and lateral ligaments that the surgeon should especially direct his efforts.

Next it may be mentioned that genu recurvatum may first show itself in the adult as the result of paralysis of the quadriceps extensor cruris, from nervous disorders, as ataxia. Mr. Shattock, quoting Albert, attributes this to the want of fixation of the knee associated with paralysis of the muscle. The body falls forward, and the line of gravity is carried in front of the knee-joint. The joint is thus brought into a condition of extreme extension, and in time the over-stretched ligaments yield and the leg becomes hyper-extended. Mr. Shattock also refers to a specimen in St. Thomas's Hospital Museum. The case was figured in Cooper and Travers's Surgical Essays. The leg was displaced forwards at right angles to the thigh, the bottom of the foot meeting the eye as the patient advanced. This condition occurred from destruction of the joint by disease.

That this deformity can occur as the result of accident is shown by a case reported by Mr. James E. Adams.[3] The patient, a man, aged forty-eight years, slipped down and fractured his patella transversely and apparently tore the posterior ligament of the knee at the same time. He got fibrous union of the patella, but whenever he tried to walk the condyles of the femur projected backwards and the limb became hyperextended to much the position found in congenital cases.

A case where the knee actually became bent forward at a right angle after a wound into the joint is reported by Mr. William Adams as occurring in the practice of Dr. Grant.[4] The injury occurred in a boy, aged eleven years, and by the time he was eighteen years of age ankylosis of the leg at a right angle anteriorly had occurred. The boy was a great rider and his exertions in this respect were supposed to have forced the tibia forwards.

In cases where the displacement forwards is the result of disease or accident, amputation or excision would usually be needful.

Cavendish-place, W.

A FORM OF

EXTERNAL RHINITIS DUE TO THE KLEBS-LÖFFLER BACILLUS APPEARING IN CHILDREN CONVALESCENT FROM SCARLET FEVER.[1]

BY C. TODD, M.D. CANTAB.

(FROM THE LONDON FEVER HOSPITAL.)

With Remarks by Professor A. A. KANTHACK, *Cambridge University.*

CHILDREN in hospital during their convalescence from scarlet fever are peculiarly liable to a certain form of external rhinitis.

Clinical history.—The first sign of anything abnormal is a slight redness of the posterior margin of one or both nostrils, usually beginning at the inner or outer angle and at the muco-cutaneous junction. The redness becomes more intense and ultimately a moist granular-looking raw surface results; this surface bleeds easily and is often covered by a crust which may almost, or completely, block up the nostril. This is more commonly the case in younger children who scratch their nostrils and so cause bleeding. There is never any formation of membrane and the process does not appear to extend backwards into the nasal cavity, but in many cases it spreads down to the upper lip in the form of an eczematous area apparently caused by the infective discharge. This discharge is usually slight and not uncommonly absent. The nostrils remain in this granular condition for a variable time—from one to four or five weeks—and then gradually resume their normal condition. During the course of this rhinitis there is a tendency to the formation of pustules on parts of the body exposed to contact with the discharge. In many cases the face has a "spotty" appearance due to the presence of several minute pustules, and at times larger pustules are seen, more especially on the hands, and apparently originating in some scratch or other slight lesion or at the edges of the nails. The rhinitis does not appear to have any effect upon the general health and is unaccompanied by any rise of temperature. There is no albuminuria or marked glandular swelling coincident with the rhinitis; but as the children are convalescent from scarlet fever the submaxillary glands in many cases are enlarged and it is difficult to say how much may be due to the rhinitis. In no case have any paralytic symptoms been observed in the 51 cases recorded, though these have been carefully looked for. This form of rhinitis appears to be contagious and spreads, though not rapidly, among young children when introduced into a convalescent ward where the children are playing together and so coming into close contact.

During the past eighteen months (from June, 1896, to December, 1898) 51 cases of this rhinitis have occurred in the wards of the London Fever Hospital. This number is not sufficiently large to allow of reliable deductions, but observations appear to show that children about the ages of three and four years are most commonly affected, above four years of age the liability appears to diminish with age, no case having occurred after the age of twelve years. The fact, however, that 51 cases occurred amongst 365 children—almost 14 per cent.—shows that it is by no means of rare occurrence. Five cases were observed during the first week after admission and in these cases the infective micro-organisms were probably in the nostrils on admission to the hospital—indeed, in several of these 5 cases the nostrils were noticed to be sore on admission. During the second and third weeks only 2 and 3 cases respectively occurred, but during the fourth and subsequent weeks there were many more. At this period the children would be up and dressed so that the rhinitis would have greater facilities for transmission.

The following cases show the situations in which the secondary pustules were commonly met with:—

CASE 1.—Pustule over metacarpo-phalangeal joint of the index finger of the left hand.

CASE 2.—Small pustule on the outer margin of the left great toe.

CASE 3.—(*a*) Pustule on the outer side of the left foot over the fifth metacarpo-phalangeal joint; and (*b*) pustule on the inner side of the left great toe.

CASE 4.—Several small pustules resembling varicella pustules on the face.

CASE 5.—Pustule on the left hand over the pisiform bone.

CASE 6.—Large pustule on the sole of the right foot. The child said that he had stepped on a small piece of tin some days before with bare feet.

Bacteriological investigation—(a) Nose.—Bacteriological examination showed the presence of the same bacillus in each of the 51 cases. Cultivations were taken from the margins of the affected nostril and grown upon Löffler's serum. Considerable difficulty was experienced at first in separating the bacillus from the large number of staphylococci present, as the bacillus when recently obtained from the nose does not appear to grow upon agar-agar or gelatin, or grows so slowly as to be completely overgrown by the staphylococcus, so that the ordinary process of plating on these media was useless. In order to obtain pure cultivations a dilute suspension of the mixed cultivation was made in broth and the water of condensation of several Löffler's serum tubes was inoculated with this suspension and then run over the surface of the serum. By repeating this process it was found comparatively easy in most cases to obtain pure cultivations. Subsequently another method was used, especially in cases where the bacillus was present in relatively small numbers; alkaline broth was inoculated with staphylococcus pyogenes albus (the organism most commonly present with the bacilli) and incubated at 37° C. for a week and then filtered through a Pasteur-Chamberland filter. This process was repeated a second time and tubes were filled with this "staphylococcus exhausted" broth in the usual manner. These tubes, when inoculated with a mixed cultivation from Löffler's serum, usually give an abundant growth of the bacillus, the growth of the staphylococcus being greatly inhibited. The bacillus

[3] Transactions of the Pathological Society of London, vol. xxv., p. 207.
[4] Ibid., vol. xiv., p. 208.

[1] This paper formed part of a Thesis for the M.D. Degree, read at Cambridge in January, 1898.

is then easily separated on serum as before. Purified in this manner the bacillus was found to be morphologically indistinguishable from the Klebs-Löffler bacillus of diphtheria. Pure cultivations were made on solidified blood serum, Löffler's serum, gelatin, agar-agar, and potato and in alkaline peptone broth and alkaline litmus broth. These were grown side by side with cultivations on the same media of an undoubted Klebs-Löffler bacillus obtained from the fauces of a case of severe diphtheria which had been followed by typical paralysis. On all the above media the growth of the bacillus was indistinguishable from that of the true Klebs-Löffler bacillus and under the microscope they presented the same characteristics when grown on the different media. The growth in old gelatin cultures with the formation of secondary foci of new growth was particularly characteristic. In alkaline glucose broth the bacillus forms acid in the same manner as the diphtheria bacillus and in about the same time; this was used as the preliminary test in differentiating the bacillus from Hofmann's bacillus, which was found in many of the noses examined.

Dr. Washbourn very kindly performed the following experiments at Guy's Hospital with a view to determining the virulence of the bacillus.

CASE 1.—Guinea pig inoculated with 1 c.c. of a 48 hours broth culture of the bacillus died in from 30 to 40 hours. A second guinea pig inoculated with 1 c.c. of a 48 hours culture died in from 36 to 48 hours.

CASE 2.—1 c.c. of a 48 hours broth culture: died in from 36 to 48 hours.

CASE 3.—1 c.c. of a 48 hours culture: died in 60 hours.

CASE 4.—1 c.c. of a 48 hours culture: died in 36 hours.

CASE 5.—1 c.c. of a 48 hours culture: died in 36 hours.

CASE 6.—1 c c. of a 48 hours culture: died in 36 hours.

CASE 7.—1 c.c. of a 24 hours culture: died in 9 days.

CASE 8.—0·2 c.c. of a 24 hours culture: lived.

CASE 9.—0·1 c.c. of a 24 hours culture: lived.

One control animal, inoculated with 1 c.c. of a 48 hours broth cultivation of Hofmann's bacillus (non-acid forming), which was found in a nose not affected by rhinitis, did not die. Thus of six guinea pigs, each inoculated with 1 c.c. of a 48 hours broth cultivation of the bacillus, all died in about 36 hours, and one animal inoculated with 1 c.c. of a 24 hours cultivation died in 9 days. Post-mortem examination showed the characteristic lesions—great œdema at the site of inoculation and hæmorrhagic suprarenals and cultivations from the seat of inoculation showed the same bacillus. With a view to further confirmation two guinea pigs were also inoculated each with 1 c.c. of a 48 hours broth cultivation previously mixed with 1 c.c. of diphtheria antitoxin (Institut Sérothérapique, Brussels) containing about 200 units. In each case the animals had merely a local transient œdema which disappeared in a couple of days. Of two control animals inoculated at the same time each with 1 c.c. of a 48 hours culture without antitoxin one died and the other had severe œdema persistent for fourteen days, but did not die. In cultivations from the fauces of the children affected with this rhinitis I have failed in all cases except 3 to find the bacillus.

These 3 cases have been excluded from these statistics for the following reasons: Two were sisters, the mother and a brother of whom were suffering from definite diphtheria at the time, and the third child had also been exposed to the infection of diphtheria and had had his pharynx examined for adenoids a day or two before the bacilli were found in the fauces. The fact that the bacillus is not found in the fauces when present in large numbers in the nostrils appears most remarkable, considering that the fauces must be almost constantly exposed to infection. In cultivations from the affected nostrils large numbers of staphylococci are found with the bacillus; these are most commonly staphylococcus pyogenes albus, pyogenes aureus and cereus flavus. Streptococci are conspicuous by their absence. In the 51 cases streptococci were found in 2 only. It is true that plate cultivations were not systematically made with a view to separating the streptococcus; but cultivations on Löffler's serum were microscopically examined so that the streptococcus would certainly not have been overlooked if present in any considerable numbers. In this respect the cultivations from the affected nostrils contrast very markedly with those from the fauces of the same cases, as the latter almost invariably show the presence of the streptococcus in considerable numbers. During the eighteen months over which these observations have extended a bacteriological examination of the fauces of every patient has been made before admission to the scarlet fever wards and during this period only one case of post-scarlatinal diphtheria has occurred in the hospital. This one case was promptly isolated, so that the children affected with rhinitis had not been exposed to any extent to infection from cases of diphtheria whilst in the hospital. On the other hand, though there have been 51 cases of rhinitis accompanied by a bacillus indistinguishable from the true diphtheria bacillus, only the one case of diphtheria mentioned above has occurred.

(*b*) *Secondary pustules.*—If examined at an early stage the secondary pustules contain the same bacillus as is found in the nostrils, generally accompanied by staphylococci. If the examination be made some time later the bacilli may have disappeared and staphylococci only are found. Stained specimens of the pus taken from one of these pustules at an early stage show large numbers of the bacilli in the bodies of the leucocytes. The pustules appear to be due to the infection of small wounds or abrasions with the infective material; they are exactly similar to the pustules seen sometimes in cases of true faucial diphtheria, which further resemble them in the fact that they contain large numbers of the bacilli. The pustules met with on the fingers in these cases of rhinitis, which commonly begin at the edges of the nails, are sometimes very troublesome, the pus escapes, and a more or less raw surface is left. This surface is not as a rule particularly tender, but is often very sluggish in healing. There is never any formation of membrane on these surfaces. Very similar pustules are occasionally met with in nurses nursing in diphtheria wards; these pustules contain the diphtheria bacillus and are not accompanied by any formation of membrane, but are usually accompanied by pain with more or less lymphangitis, which is not the case with the pustules met with in cases of rhinitis. I have examined a considerable number of children convalescent from scarlet fever with a view of determining if the bacillus ever occurs in the nostrils without the characteristic lesion. In one case it was found in the apparently healthy nose of a child who was in the same ward as children suffering from rhinitis; and also in the case of a boy whose nose was apparently healthy, but who had a large pustule containing the bacilli on the sole of his foot, and who was also in a ward with children suffering from rhinitis. In these two cases the bacillus was acid-forming, but its virulence was not tested by experiments on animals. In 36 of the children examined Hofmann's bacillus was found in the nose, occasionally together with the diphtheria-like bacillus in cases of rhinitis, but generally in cases with a profuse clear nasal discharge and without any soreness of the nostrils. This bacillus, however, is widely distributed and is commonly found in the clear nasal discharges of otherwise healthy school children.

Recapitulation and Remarks.—1. Children convalescent from scarlet fever in hospital are very liable to a certain form of external rhinitis, often accompanied by the formation of secondary pustules on various parts of the body. 2. This rhinitis though not membranous is associated with the presence of the Klebs-Löffler bacillus in the nostrils, this organism being absent from the fauces. 3. It is contagious as such, but has not been observed to give rise to faucial or laryngeal diphtheria. 4. It is unaccompanied by rise of temperature, albuminuria, or marked glandular enlargement. 5. It appears to be limited to children under thirteen years of age and has been most frequently observed at the ages of three and four years. The fact that the bacillus, though present in the nostrils in large numbers and causing a local lesion, does not give rise to any constitutional symptoms or to faucial or laryngeal diphtheria, suggests that its virulence is modified to a remarkable extent. It is virulent to guinea pigs when inoculated subcutaneously, but this is no criterion of its virulence to the human being, as was shown by Dr. Klein in the case of diphtheria bacilli taken from the fauces of patients suffering from diphtheria. Why the bacillus limits itself to the nostrils and does not invade the tonsils is very hard to see, as the tonsils must be liable to repeated infection both from the nasal passages direct and through the mouth. It appears not improbable that under certain conditions this feebly virulent bacillus may acquire a higher degree of virulence and this point possesses a peculiar interest in view of the large number of cases of diphtheria met with after scarlet fever. I am greatly indebted to Dr. Sidney Phillips and to Dr. Washbourn, in whose wards the above observations have been made, and also to Dr. Washbourn for

his kindness in determining the pathogenic effects of the bacillus.

Remarks by Professor KANTHACK.—As Dr. Todd read the above paper during an Act for the M.D. degree I allow myself the privilege of adding a few critical remarks which in substance were offered at the time and which are intended to fill some gaps in a valuable piece of work. It is important in connexion with Dr. Todd's paper to allude to the observations of Dr. Cautley,[2] who examined the nasal secretion of persons suffering from acute febrile nasal and naso-pharyngeal catarrh and found the bacillus coryzæ segmentosus, an organism which morphologically and on artificial cultivation is certainly allied to the diphtheria bacillus. Unfortunately Dr. Cautley did not perform animal experiments or attempt any chemical tests. Certainly his organism was not a "Hofmann's bacillus," nor was it a typical diphtheria bacillus. Next, mention must be made of the numerous cases of fibrinous rhinitis in which diphtheria bacilli or organisms indistinguishable from diphtheria bacilli have been found. It must suffice to allude to the published works of Abbott,[3] Freeman,[4] Czemetschka,[5] Concetti,[6] Stamm,[7] Meyer,[8] Gerber and Podack,[9] and Pluder.[10] Rhinitis fibrinosa is a chronic affection which, as a rule, remains local and does not give rise to a clinically recognised diphtheria, but the bacillus occurring in this lesion is now generally acknowledged to be the Klebs-Löffler bacillus. Further, bacilli resembling diphtheria bacilli, but not Hofmann's bacilli, are found with great frequency in many forms of ulceration of the skin, gangrene, stomatitis, cancrum oris, and noma. Together with Mr. J. W. W. Stephens I have examined systematically a number of such cases and have separated in all cases of cancrum oris and noma an organism so closely resembling Löffler's bacillus that although in most cases it was not virulent I have not hesitated to place it provisionally with the diphtheria bacillus. Recently Freymuth and Petruschky[11] have reported that in cases of noma they have obtained the diphtheria bacillus. I hope soon to find the necessary leisure to publish my own researches, but wish here to point out that in many forms of chronic and impetiginous ulceration of the skin it is easy to find bacilli resembling the diphtheria bacillus, in all respects excepting virulence, so closely that I see no reason to separate them as pseudo-forms, all the more since they all differ strikingly from Hofmann's bacillus and since competent observers now begin to recognise that acid formation, metachromatism, Neisser's staining reaction, appearances on gelatin and agar-agar, and virulence are no more certain criteria for the diphtheria bacillus than appearances on gelatin, indol reaction and virulence are certain criteria for the cholera vibrio. I have maintained for some time that bacilli actually and not merely distantly resembling the diphtheria bacillus are found frequently in the throat and elsewhere in chronic ulceration, impetigo, cancrum oris, &c., and that in many cases by continued growth these bacilli may be so altered as to resemble the diphtheria bacillus still more closely and even to acquire pathogenic properties. The diphtheria bacillus is in my opinion widely distributed, frequently in modified forms, it is true, but still in such forms which, except by artificial and imaginary criteria, such as would not be recognised in the case of other micro-organisms, cannot be separated from the Klebs-Löffler bacillus, which even under the best conditions is a highly polymorphic organism. I therefore consider the work of Dr. Todd of all the greater importance, since it is a further contribution to the view which is gradually gaining ground that the diphtheria bacillus is found in many lesions which are not "diphtheria,"[12] and that the various tests, generally enumerated, do not suffice to distinguish the various modifications from the "text-book variety" of the Klebs-Löffler bacillus. It is unnecessary to draw attention to the bearing which such a view has upon the etiology and pathology of diphtheria.

RECURRENT CARCINOMA OF THE FEMALE BREAST ENTIRELY DISAPPEARING UNDER THE PERSISTENT USE OF THYROID EXTRACT CONTINUED FOR EIGHTEEN MONTHS.

BY FREDERICK PAGE, M.D. EDIN., M.R.C.S. ENG., SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE, &c.;

AND

WILLIAM H. BISHOP, M.B., B.S. DURH.

IN December, 1895, Mr. Page was asked by a former house surgeon of his, Dr. Bishop of Wylam, to see with him a woman, aged sixty-one years, who was suffering from carcinoma of the left breast of some six months' duration. The general health was very much impaired. The growth was situated in the upper part of the breast and was of the size of a hen's egg and both the axillary glands and their lymphatics were affected. On Jan. 7th, 1896, the breast was removed together with the axillary glands and fat, the lymphatics, and the pectoral fascia. In April there was a recurrence of the disease in the neighbourhood of the cicatrix and on July 18th several nodules, varying in size from that of a pea to that of a walnut, were removed. A portion of these growths was sent to the Clinical Research Association and reported on as follows on July 29th: "Both specimens show a soft carcinomatous growth, with small alveoli and very scanty stroma. At first sight it might be mistaken for sarcoma but the mode of growth at the edge and the invasion of the fatty tissues is unlike that of sarcoma. In the section of the skin the dense fibrous tissue in the corium prevents any very rapid multiplication of the cancer cells." Three weeks after this second operation other nodules appeared in the scar and later a group developed below it and in the subcutaneous fat. Further interference was declined and, indeed, did not seem to be feasible. The nodules steadily increased in size and number. In September, 1896, at the suggestion of Dr. Bishop, thyroid extract was given quite as a forlorn hope. At first 3 gr. were taken daily and the dose was gradually increased till 15 gr. could be taken daily. During the eighteen months that the treatment was persistently followed it was found necessary occasionally to suspend the use of the drug for some days on account of its toxic effect. The patient is now quite well. She has gained flesh and health to such an extent that it is difficult to believe that she is the same person who was operated upon two years and four months ago. There is no trace of the disease to be discovered.

Remarks by Mr. PAGE.—Such are the facts. It may be that this case is a vagary of recurrent cancer, but taken in conjunction with the cases of recurrent carcinoma reported by Dr. G. Beatson of Glasgow, in all of which thyroid extract was given, I consider it to be one of great importance and interest, so much so that I intend to try the persistent administration of thyroid extract in every case of recurrent or inoperable carcinoma of the female breast coming under my observation. In due course I trust to record the results of the experiment and in the meantime the case is reported in the hope that it may induce others to give the treatment a trial.

Remarks by Dr. BISHOP.—I am much indebted to Mr. Page for permission to add the following remarks. When despite the completeness of the first operation the growth returned three months later and when only three weeks after the second operation it again made its appearance the case looked hopeless. It was then that in sheer desperation I determined to try thyroid extract, having read Dr. Beatson's papers,[1] notwithstanding his opinion that it has "little effect when given alone." Mr. Page cordially approved of the experiment. At first it did not seem to have any effect but it was soon apparent that no increase in size was taking place and the patient maintained—rightly I think—that the growths were softer. In the spring of last year, however, about six months after the treatment was commenced a lump appeared above the operation scar and grew rapidly till it

[1] THE LANCET, July 11th, 1896, p. 104, and July 18th, 1896, p. 162.

was as large as a walnut when it seemed to cease growing. I did not examine the breast from Christmas of last year (when in addition to the growth just mentioned there were a number of nodules in and about the scar and a group below it in the subcutaneous fat) until April 18th last, when I was amazed to find that every trace of the growths was gone. I at once informed Mr. Page and he immediately went to see the patient and confirmed my observation.

It is always dangerous to draw conclusions from a single case but if thyroid extract had no effect upon the growths to what is their disappearance due? And if beneficial results from its use are, as Dr. Beatson maintains in his papers, dependent on a previous oöphorectomy why should it alone not succeed after the menopause has been passed? If it is really, and of itself, of utility in carcinoma of the breast then it ought also to be of service in carcinoma of other parts of the body, and I suggest its trial in inoperable cases when the growth is situated elsewhere than in the mamma. In this connexion also it would be interesting to know whether the subjects of thyroidectomy or those in whom that gland is functionally inactive are peculiarly liable to carcinomatous growths. I am not aware that such is the case. It would also be interesting to get information as to the condition of the thyroid gland in the subjects of this disease. How the thyroid extract acts it is very difficult to surmise. Whether it alone, or in conjunction with the menopause (either naturally or artificially produced), tends to promote a fatty degeneration of the carcinoma cells, or by stimulating the lymphatics to remove the carcinomatous material (to which theory there would seem to be obvious objections), or by increasing metabolism enables the phagocytes to cope with the disease, or acts in some other way, further data can alone supply facts for a decision.

Not the least puzzling feature of the above case is the development of a growth during the treatment. At the time, however, the patient was suffering great anxiety owing to the illness of her husband and was constantly up at night. The general health suffered much and it is possible that the thyroid tabloids were neglected. What we learn from this, and I think also from Dr. Beatson's cases, is that to do any good the administration of thyroid gland must be pushed to its full physiological effect and continued over a great length of time.

A CASE OF DECAPITATION.

BY T. EDWARD SANDALL, B.A., M.B., B.C. CANTAB.,
MEDICAL OFFICER OF HEALTH OF ALFORD; LATE HOUSE PHYSICIAN AND HOUSE SURGEON AT CHARING-CROSS HOSPITAL.

THE operation of decapitation is one which is so rarely required in midwifery practice that I think it desirable to report the following case. I have no means of ascertaining statistics as to the frequency of cases in which decapitation has been required, but I feel sure that it is an operation which it is very seldom the lot of a general practitioner to perform. A neglected shoulder presentation in which version is impossible is usually described as the condition which renders decapitation justifiable and necessary, but in the case I am about to describe the presentation was more rare and complex, being a true transverse presentation, the chest being the presenting part, with both arms prolapsed. The history of the case is as follows.

About 10 A.M on March 21st, 1898 I received a message from Mr. G. Bosson of Alford, asking me to come to assist him in a difficult midwifery case in a village about three miles away. On arrival at the house I learned the following particulars. The patient was a married woman who had previously had two children born at full time, the labours having been natural and fairly easy. She had had good health during her pregnancy, was at her full time, and there were no special circumstances about the case. Labour had begun on the afternoon of March 19th; the pains had gradually become stronger during the night and the membranes ruptured about 10 A.M. on the 20th, when the nurse wished to send for Mr. Bosson, who had been engaged to attend the patient. The husband, however, declined to go for the medical man, urging that his wife was not "bad enough," and that she would get over it all right without medical assistance as she had done before. The pains continued all day and all the next night, and at about 8 A.M. on the 21st, as the patient seemed to be making no progress and was becoming exhausted, the nurse insisted on the husband fetching the medical attendant. Mr. Bosson saw the case for the first time about 9 A M. on that day and on examination found a transverse presentation as described below. He at once attempted to perform podalic version, but finding it impossible to reach a leg without an anæsthetic and recognising the difficult nature of the case he shortly afterwards sent for me to assist him. On my arrival I examined the patient and found the following condition of things. The right hand of the child was projecting outside the vulva, while the left hand could be felt immediately within the vagina, and on passing the finger up the sternum could be felt presenting, the chest being firmly pressed down by the contraction of the uterus. The head lay in the left iliac fossa, the neck being hyper-extended, and the chin could be reached by the finger with difficulty; the trunk and legs lay to the right, the only part which could be felt being the front of the abdomen, and it was quite impossible to touch a foot or a leg. The diameters of the pelvis appeared to be normal. The patient was somewhat exhausted, the pulse being 120, somewhat small, and regular, but on my proceeding to administer chloroform by a Junker's inhaler she took the anæsthetic well, expressing herself thankful to get some relief from the pain. When she was fully under chloroform Mr. Bosson attempted to reach a foot or a leg with the idea of performing podalic version, but after a considerable time he gave up the attempt and as an alternative tried to bring the head down by traction with the finger in the mouth, but the uterus was by this time so contracted down that he was unable to move the child in any way. He then requested me to try while he continued the administration of chloroform as, owing to a somewhat greater length of finger, I had a slightly longer reach. I found it quite impossible, however, even with the whole hand in the vagina to get high enough up to reach a leg, and the uterine contractions caused so painful a cramp of the fingers after a time that I was obliged to desist, and I found it equally impossible to bring down the head though I exerted very forcible traction by a finger in the mouth which could be reached with great difficulty. The patient meanwhile was becoming more exhausted, the pulse-rate rising to 140 and decapitation seemed to be the only possible way by which to bring about delivery. I therefore drove home to fetch a Ramsbotham's hook, which instrument I fortunately possessed, the patient being allowed to come round from the anæsthetic. On my return at about 2 P.M. I again administered chloroform, but the tonic contraction of the uterus was now so great that Mr. Bosson found it impossible to reach the neck of the child and requested me to try while he attended to the administration of the anæsthetic. After some time, passing the whole hand into the vagina, I managed with difficulty to pass my forefinger in front of the neck and hook it round, so drawing the neck down as much as possible. I then passed the decapitating hook up, point to the left, along the forefinger of my right hand, turning it backwards over the neck. Withdrawing the right hand I passed the left forefinger up to meet the point of the hook and, thus guarding against injury to the soft parts, by a sawing motion combined with traction I decapitated the child. By slightly pulling the arms, assisted by external pressure, the body of the child was now easily extracted and the head was delivered by means of the forceps. The patient, whose pulse-rate was 170, appeared to be very exhausted, but she gradually rallied as she recovered from the anæsthetic, the pulse-rate falling to 140. The placenta was expressed in about ten minutes; it came away without any trouble and there was very little hæmorrhage. The child was a healthy male, of rather large size but with no abnormality whatever, and apparently had lived up to the time of labour. I left the patient under the care of Mr. Bosson at about 3.30 P M. in a fairly satisfactory condition considering the strain she had gone through and the length of time she was under chloroform, but unfortunately she never rallied from the shock. I did not see her again, but I learned from Mr. Bosson that she gradually sank and died on the morning of the 23rd, about thirty-six hours after delivery.

Apart from the operative interference required I think this case worth recording on account of the extreme rarity of the presentation. Dr. Galabin in his "Text-book of Midwifery" states that he has never yet met with a case in which the

foot or knee could not be reached, but it was absolutely impossible to touch either in this case even with the patient under chloroform pushed to the extreme surgical degree. Cephalic version was rendered impossible by the firm contraction of the uterus down upon the fœtus and decapitation therefore became the only method of treatment. With regard to the operation itself, although I need hardly say that I have never performed it before or seen it performed I found very little difficulty in carrying it out when once the neck was encircled by the finger. The presence of both arms in the vagina and the impossibility of pushing them up out of the way interfered to some extent, however, by allowing very little room in which to work, and a good deal of care was required in passing the decapitating hook to prevent any injury to the maternal soft parts which, fortunately, I succeeded in doing.

Being in the country and therefore having no access to a good library I cannot lay claim to having studied the literature of the subject, but the text-books which I possess—Galabin, Playfair, Lusk, and also Ramsbotham—do not describe the peculiar form of presentation which was found in this case. In all the forms described in these text-books the presentation of the head or feet with the hands is mentioned and version in such cases is usually possible, but a true transverse presentation with marked opisthotonos and both arms prolapsed is not mentioned and is, therefore, I conclude, exceedingly rare. The usual causes of transverse presentations as generally given were here conspicuous by their absence. The child was a normal, healthy, living male at full term and not a dead, premature, or macerated fœtus as one might expect to find. The mother was a well-built, healthy woman with no obvious pelvic contraction, as her two previous easy full-term labours show, and there was no other maternal abnormality to cause obstruction to labour. I greatly regret the unsuccessful termination of the case, but I feel convinced that the patient lost her life owing to the neglect of the husband to send for medical aid at the proper time. If the patient had been seen earlier version would probably have been possible under chloroform, but the long delay no doubt complicated the presentation, necessitating the operative procedure I have described with, unfortunately, a fatal result.

Alford, Lincolnshire.

A CASE OF TETANUS; EARLY AMPUTATION; RECOVERY.

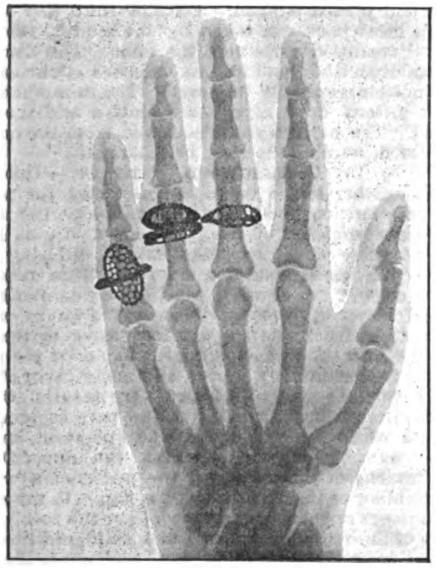
BY W. N. CLEMMEY, M.R.C.S. ENG., L.R.C.P. LOND.,
HONORARY SURGEON TO THE BOOTLE BOROUGH HOSPITAL, LIVERPOOL.

A MAN, aged twenty-nine years, was admitted to the Bootle Borough Hospital on May 25th, 1892, under the care of Mr. R. J. Sprakeling, suffering from a compound comminuted fracture of the bones on the outer side of the left foot (the cuboid and the fourth and fifth metatarsals), caused by the wheel of a cart going over it. Suppuration with separation of the dead bone followed, during which time the cavity of the wound was well sprayed with carbolic lotion and dusted with iodoform powder and the foot enveloped in a bran poultice which was frequently renewed. An "iron" mixture was prescribed. The patient continued in fair health and spirits up to June 5th—i.e., eleven days after admission—when he had slight trouble in swallowing a piece of orange pulp. On the 6th this difficulty was emphasised with regard to everything but fluids, the patient complaining that his tongue and the back of his mouth felt stiff. Other symptoms quickly made their appearance. His pupils were widely dilated and slight nystagmus was noticeable but sight, hearing, and taste were normal. He had some spasmodic contraction of the temporals and masseters, also of the left sterno-mastoid, preventing him from separating his teeth more than half an inch apart and keeping his head fixedly turned towards the left side. The reflexes were as follows:—Abdominal and epigastric: on right side when first tried +, but soon tired; on left side +. Cremasteric: right +; left very much −. Patellar: right +. Plantar: right +. Ankle clonus was present. The organic reflexes were normal. Owing to all the symptoms pointing to the onset of tetanus the foot was removed immediately by amputation through the middle of the leg. The patient took the chloroform well. On the 7th the patient was about the same. On the 8th the spasms of the muscles of the jaw seemed worse although the patient had no trouble in swallowing liquids. The reflexes became easily tired and perspiration was profuse. The patient slept well. On the 9th slight opisthotonos was noticeable but the reflexes were not so excitable; speech was still impaired and it took the patient six seconds to say the alphabet. On the 15th owing to the appearance of a bromide rash, the administration of this drug, of which he had been taking 20 gr. three times a day since June 6th, was stopped, and 10 minims of tincture of hyoscyamus and 20 gr. of chloral hydrate were substituted. On the 17th he was able to move his head slightly from side to side and there was improvement in his speech, the alphabet being said in five seconds. On the 19th two hypodermic injections of extract of physostigmine (♏ x = gr. ½) were administered. In the evening the patient was able to open his mouth more widely and to speak better and could sit up in bed. On the 20th three more injections were administered, but owing to the patient being very depressed, restless, and troubled with perspiration they were stopped. On the 21st stiffness of the muscles reappeared and as he had had no sleep for some days ¼ gr. of morphia was given with good result, the patient expressing himself as being "better than ever he had been." On the 23rd he was able to sit up to his meals which now consisted of tea, bread-and-butter and "slops." The reflexes were still exaggerated and ankle clonus was present; the stump when dressed twitched convulsively; towards evening the patient became very restless, especially during sleep. On July 5th solids were eaten without any trouble and the alphabet was repeated in five seconds. On the 13th the reflexes were almost normal; there was no ankle clonus and the muscles were soft. The alphabet was gone through in four seconds. When seen on Sept. 9th the patient was quite well.

The present theory of the disease—viz., that the bacillus is localised to the point of inoculation and that a ptomainic poison is generated at that spot, is absorbed into the blood, and gives rise to the muscular contractions characteristic of the disease owing to irritation of the central nervous system—is to a degree illustrated in the foregoing case. There can be no doubt that in this case the bacillus found entrance at the time of injury, seeing that after the patient's admission the wound was most assiduously plied with antiseptics and that all the wounds in the same ward were perfectly healthy, and I think it is a fair presumption that if this process had not been carried out the disease might have shown itself sooner and have been more virulent in type. The first symptoms detected were pharyngeal in character and were fortunately early recognised and the removal of the part inoculated was performed at once. In spite of this, however, *the symptoms for the first four days afterwards became intensified*, the jaw spasms becoming worse, and on the fourth day after operation there was opisthotonos. A further interesting fact in this case to be noted is that the skin reflexes were on excitation very markedly exaggerated but that after once or twice responding they became imperceptible,

The above facts are rather suggestive that the ptomainic poison either becomes (after its area of generation is removed) for a few days more virulent when in the blood, or so weakens in a progressive way the general physiological resistance of the system, or else that it has a progressively paralysing action upon the reflex inhibition centres in the brain and cord. It may further be, as has been suggested, that there are in the tetanic poison two or more substances of different constitution, one the true tetanic poison of what may be called a constant pathogenic index acting in a definite manner upon the motor cells, the others acting in a progressive way upon the general system and upon the reflex inhibition centres. The fact that the skin reflexes were first exaggerated and then so easily tired seems to suggest especially some disturbance of the sensory portion of the reflex arc. This seems probable from the fact that in tetanus the motor apparatus—i.e., the motor nerves and muscles—is shown to be capable of prolonged tetanic action—the muscles of the face by their contraction forming the risus and the masseters forming the lockjaw.

Bootle, Liverpool.



SHORT EXPOSURES IN PRACTICAL X RAY WORK.

BY C. THURSTAN HOLLAND, M.R.C.S. ENG., L R.C.P. LOND.,
HONORARY MEDICAL OFFICER IN CHARGE OF X RAY DEPARTMENT, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

ONE of the great disadvantages in x ray work is the length of exposure necessary to get a good photographic result. Macintyre (of Glasgow) and Webster (of London) have both done "snapshot" work, using large coils; but the large size, and consequently great weight, of these coils is a drawback, as it is almost impossible to take an 18-in or 20-in spark coil to the bedside of a patient, and in addition the cost of these large coils is very considerable. Besides this, short exposures are very advantageous in many ways: (1) the patient has not to be kept still for so long a time, and to anyone in pain this keeping still is very irksome; (2) it is of advantage in the case of young children who cannot understand the necessity of absolute immobility; (3) the risk of setting up x ray dermatitis, &c., is smaller; and (4) the time of the operator is saved.

Lately, working with 6-in and 10-in coils, I have obtained good results in many cases with compartively short exposures and I now use this method in nearly all cases. Working with a 6-in coil the adult hand represented by Fig. 1 was taken with an exposure of fifteen seconds, whilst with a 10-in. coil the knee and ankle-joints of an

FIG. 1.

Skiagram of adult hand with rings. Palm on plate. Exposure 15 seconds.

FIG. 2.

Skiagram of knee-joint of adult male. Inner side on plate. Exposure 30 seconds.

FIG. 3.

Skiagram of ankle-joint of adult male. Inner side on plate. Exposure 30 seconds.

FIG. 4.

Skiagram of elbow-joint of adult showing congenital deformity. Exposure 30 seconds.

adult male shown in Fig. 2 and Fig. 3 were obtained with exposures of thirty seconds each and the elbow-joint of an adult congenitally deformed (Fig. 4) was taken in thirty seconds. All these results compare favourably with similar ones obtained by exposures reckoned in minutes.

My method is as follows. Having tested the tube with the screen to see that it is working at its best—and in my opinion a tube giving a good screen result can always be depended upon to give a good photographic result—the exposure is made. Then the plate (usually a "Cadett-lightning") is put into a weak rodinal developer (1 part to 64 or so of water) and left in the dark room. In the course of a few hours the plate is taken out and fixed. Sometimes, in order to obtain the best possible print, the plate must be intensified, but as a rule this is not necessary. The length of time developing is no disadvantage, as for immediate purposes the screen is nearly always sufficient and the plate can be left to develop itself, so that there is no waste of the operator's time.

In addition to the skiagrams shown above I have others of a hand taken in five seconds, a thick adult chest and shoulder taken in three minutes, and so on. I have used Apps-Newton coils with the ordinary interrupters and tubes supplied by Newton and Co.

Liverpool.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

HAMPSTEAD HOSPITAL.

A CASE OF PERFORATING APPENDICITIS; GENERAL PERITONITIS; ABDOMINAL SECTION; RECOVERY.

(Under the care of Dr. E. COLLINGWOOD ANDREWS.)

A BOY, aged twelve years, was on Dec. 21st, 1897, admitted to the Hampstead Hospital for acute peritonitis. Late on the evening of Dec. 18th he complained of feeling chilly and unwell and on the following morning he had a dull pain all over the abdomen with sickness and a shivering fit. On the 20th the pain became much more acute and no food or medicine could be taken without vomiting. The bowels acted moderately. On admission to hospital the temperature was normal and the pulse, which was small and hard, was 115. Pain and retching were incessant and the face was flushed and anxious. The whole of the abdomen was rigid and abdominal respiration was absent. No definite tumour could be discovered. The pain was referred to the region of the umbilicus and there was no special tenderness about McBurney's spot. The rectum was empty and much "ballooned," but afforded no clue as to the nature of the attack. It was apparent that the case was one of acute general peritonitis due to perforation of a viscus and the early history appeared to point to the appendix as the seat of the disease. Dr. Andrews decided to operate forthwith and gas and ether were administered by Dr. Cook, while Dr. Ware assisted the operator. The usual incision, with its centre at McBurney's spot, was made, and on opening the peritoneal cavity the whole of the parietal and visceral layers were found to be much inflamed and a strong fæcal odour was observed. Between the coils of intestine in the right pelvic fossa there was a collection of very foul pus, which was carefully prevented from reaching the other portions of the abdominal cavity. The appendix was adherent to the small intestine and was with difficulty freed and brought out of the abdominal opening. Its distal two-thirds were much inflamed and thickened and half an inch from the tip there was a perforation of the size of a pea through which fæcal matter was oozing. The meso-appendix, having been ligatured in three portions, was divided and a ligature was passed round the appendix a quarter of an inch from the cæcum. The appendix was now cut through and the mucous surface of the stump was touched with pure carbolic acid. Irrigation was not employed, but the abdominal cavity was carefully sponged and a large indiarubber drainage-tube was passed down into the pelvis. Further, in order to shut off the abscess cavity, it was well packed round with iodoform gauze and the abdominal wound was sutured in the usual way. For two days subsequently to the operation there were persistent vomiting and much restlessness. The temperature remained normal and the pulse about 120. Nothing was taken by the mouth except a few teaspoonfuls of hot water; *per rectum* nutrient enemata of port wine and Valentine's meat juice were given and there was injected hypodermically $\frac{1}{100}$ gr. of strychnia, with $\frac{1}{6}$ gr. of morphia added when there was much pain. There was a free discharge of dark foul pus and the dressings had to be frequently changed; the gauze packing was taken out on the second day. Flatulent distension was relieved by the passage of a rectal tube and on the second day there was a watery and offensive stool. On the third day a little Valentine's meat juice was taken by the mouth, the pulse and general condition remaining the same. The discharge of pus then diminished and lost its offensive odour and the general condition gradually improved. The tube was finally taken out fifteen days after the operation and the sinus soon closed. The patient was discharged from the hospital perfectly cured, wearing the usual belt and pad.

Remarks by Dr. COLLINGWOOD ANDREWS.—This case affords yet another lesson as to the necessity for prompt operative interference in cases of perforation peritonitis. I refrained from irrigation of the peritoneal cavity as I considered that there would be grave risk of diffusing fæcal matter and that no irrigation could succeed in rendering aseptic the coils of bowel which were already contaminated. I attempted, however, to isolate them by the gauze packing and to drain the inevitable suppurating cavity by the tube. No doubt the formation of a peritoneal flap over the stump of appendix is theoretically correct and under other circumstances I have done this with satisfactory results. In the present case the general condition of the patient precluded any measure which would lengthen the operation, and in a subsequent case, in which I removed the appendix for recurrent attacks of inflammation, the peritoneum was too adherent to allow of the formation of a flap. In my experience the absence of the flap does not affect the result. The ballooning of the rectum is unusual in a child, and, contrary to a recent assertion, it did not disappear under the anæsthetic. In this case, as in other abdominal cases, I was much impressed by the aid afforded to the surgeon by the charting of the pulse in addition to the temperature on one of Mr. Mayo Robson's clinical charts.

CHRISTCHURCH HOSPITAL, NEW ZEALAND.

FIVE CASES OF ABDOMINAL SURGERY AND A CASE OF HYDATID TUMOUR OF THE BRAIN.

(Under the care of Dr. COURTNEY NEDWILL.)

THE six cases which we publish below are excellent examples of the valuable results which can be obtained by modern surgical treatment and they demonstrate clearly, if any proof were needed, that surgery at the antipodes will not suffer in comparison with the surgery of Europe. Probably the most interesting of the cases are the first and the last. The case of removal of a stone from the common bile-duct shows how firmly fixed these calculi may be and how much the obesity of the patient increases the difficulty of the operation. The case of hydatid of the brain illustrates the accuracy with which tumours of certain portions of the brain can be localised. In comparatively few cases have hydatid cysts of the brain been treated surgically with success. We hope to refer to this subject shortly.

CASE 1. *Stone in the common bile-duct.*—A married woman, aged thirty-three years, was admitted to the Christchurch Hospital, New Zealand, on April 27th, 1897. For three years she had been subject to attacks of violent colic at varying intervals. The pain had been referred to the region of the gall-bladder and had been followed by very slight jaundice and high coloured urine. She had never discovered gall-stones in the fæces although she had looked for them. She was on admission nine weeks pregnant. She was free

from jaundice and there was no bile pigment in the urine. On May 4th the abdomen was opened on the right side but the patient was so very stout that the incision had to be prolonged upwards and downwards before the gall-bladder, which was only slightly distended, could be reached. After great efforts a stone could be only just reached by the tip of the finger in the common duct. The abdominal wound was now extended as high as the cartilages of the ribs would permit and by lifting them up with a broad retractor Dr. Nedwill was able to get the stone isolated in the duct between the index and middle fingers, but he could not move it either up or down. He tried to needle it next but he could not fracture it. By forcibly lifting up the ribs he could just get sight of that part of the duct between his fingers containing the stone. He therefore packed strips of gauze round his fingers and slit up the duct with a scalpel. The stone was so tightly embedded that it was with difficulty extracted. The opening in the duct was carefully sutured by a fine continuous silk ligature and the abdomen was closed. The stone was of the diameter of a hazel nut but longer. On May 18th the temperature had been normal since the operation. The patient suffered from neither pain nor discomfort. On June 4th she was discharged from the hospital.

CASE 2. *Acute intestinal obstruction by a Meckel's diverticulum.*—A girl, aged sixteen years, was admitted to the hospital on Dec. 28th, 1896. She was quite well and healthy on the 24th, but on the 25th she was out of sorts and unable to take her food. Her bowels were very costive and were only slightly acted on at the latter date. Since then they had not been moved and no flatus had been passed by the anus. On the 30th, when she was transferred to Dr. Nedwill's care, vomiting was very frequent, the pulse was small, and the abdomen was greatly distended. No information was gained by rectal examination. The temperature had been subnormal but was now 100° F. Dr. Nedwill opened the abdomen in the middle line and after some search found the bowel on the right side to be congested and enormously distended up to a certain point and beyond this collapsed and empty. A cord-like band, which ran from the umbilicus towards the right side, was divided between double ligatures and the obstruction was relieved. There was some delay in convalescence owing to suppuration in the abdominal scar, but the patient was discharged from the hospital in good health on March 13th.

CASE 3. *Large multilocular colloid ovarian tumour weighing 16 lb. containing only about half a pint of thick viscid fluid.*—The patient was a married woman, aged twenty-two years, with a tuberculous history. She was small and about 5 ft. 2 in. in height and had a normal weight of about 6½ st. She was admitted to the hospital on April 20th, 1897. She had one child two and a half years old. The last menstrual period occurred eighteen months previously to admission. She had a large ovarian tumour, which was tense and solid to the feel, but which appeared at some points as if it were fluctuant. The measurement round the abdomen was 32 in. The umbilicus was bulging. The cervix was badly lacerated and the uterus was small and moveable. On the 27th Dr. Nedwill opened the abdomen and found the peritoneum to be adherent to both the abdominal wall and omentum. After exposing the surface of the tumour and plunging into it a large Wells's trocar only one or two tablespoonfuls of thick gelatinous fluid escaped. The tumour was so huge that Dr. Nedwill thought that he would try to break it up from the centre, but it was so solid that he quickly abandoned this idea and extended the abdominal wound close down to the bladder and as high up as the ribs. The tumour was, however, so bound down by large adhesions containing enormously distended vessels stretching all over it like extended fingers that before he could deliver it many ligations had to be applied. Instead of dividing these bands between double ligations he found he could more quickly free the tumour by clamping the bands on the tumour side and only ligaturing the other end. There were so many of these adhesions that all the long locking forceps in the hospital were engaged on them. Dr. Nedwill was then able to turn out the tumour, but it brought away with it a large quantity of adherent bowel. The bowel having been carefully separated the pedicle was easily reached and ligatured. It was a very small pedicle, not larger than an ordinary thumb. The patient was now in such a collapsed condition, although scarcely any blood had been lost, that Dr. Nedwill hurriedly mopped out the pelvis, into which he thought some of the thick fluid might have escaped, and closed the abdomen. During the operation the patient had had two hypodermic injections of strychnine and about half a pint of saline solution was injected into the cellular tissue below the left breast. It was, however, only by lowering the head and holding it down over the end of the operating table that her pulse was kept going. Mr. Edward Gane, the assistant house surgeon, the anæsthetist, had to do this several times, as on restoring her to the horizontal position the pulse failed. It may be mentioned here that on a former occasion Mr. Gane, in Dr. Nedwill's opinion, averted a fatal termination by having recourse to this same method in a case where Dr. Nedwill removed a large tuberculous kidney. On the 28th the patient was doing fairly well. The pulse was rather small and rapid. The temperature suddenly rose to 103° F. during the night, but only for a short period. On May 2nd the temperature showed a slight rise at night. There was some offensive discharge from the rectum, but otherwise the patient was comfortable. On the 4th an abscess under the left breast was opened; it contained gas. On the 7th the abdominal wound had healed. The temperature was still high at night. The phthisical mischief at the left apex was progressing. On the 18th there was still a slight rise of temperature at night. Some foul-smelling discharge from the bowel took place. There was slight incontinence of the rectum, but no cause was ascertainable. The temperature remained elevated at night from April 28th to May 24th. On May 20th the abdominal wound was swollen and red with pus issuing from the scar; a good-sized abscess was evacuated. After this the temperature remained normal. The patient put on flesh rapidly and was discharged from the hospital on June 23rd.

CASE 4. *Tubal pregnancy.*—A married woman, aged thirty-five years, was admitted to the hospital on June 15th, 1896. She had had fourteen children without trouble occurring during any pregnancy. She had had no miscarriages. She had menstruated regularly till six weeks before admission, but she was then suddenly taken with pain across the abdomen on getting out of bed in the morning. For a month this pain continued, but for the past fortnight she had been free from it. She had had a vaginal discharge for the past five weeks and two weeks before admission she passed "a lump of flesh." On abdominal examination a well-marked tumour was seen on the left side extending from Poupart's ligament to just below the level of the umbilicus. The swelling was fixed in position and resonant on percussion. On the 17th Dr. Nedwill opened the abdomen and found that the peritoneum, omentum and tumour were all closely adherent together. Several coils of intestine had to be stripped off the surface of the tumour and in one place part of the sac had to be left adherent to the bowel. A good many adhesions were brushed off with a soft sponge but several had to be tied. This mass, which was of about the size of a cocoa-nut, was then turned out and was found to consist of coagulated blood in the broad ligament with a tubal fœtation. As the left ovary was cystic, it and the tube and the broad ligament were removed. The abdomen was closed. The temperature remained normal throughout and the patient was discharged from the hospital on July 31st. Some months after the operation she returned with almost all the usual symptoms of Graves's disease well-marked. This condition was present before the operation but was not well-defined.

CASE 5. *Tubal pregnancy of the left side and ovarian cyst of the right ovary.*—A woman, aged thirty years, was admitted to the hospital on October 24th, 1896. The patient stated that she had menstruated early in August but not since then. For the past six weeks she had had a sanguineous discharge from the vagina. The abdomen was distended in both flanks but much more so on the right than on the left side. The uterus was felt in the middle line. Douglas's pouch was occupied by a fairly large-sized tumour. The fornices were filled up with a swelling continuous with that felt in the abdomen. The cervix was pushed forward. Dr. Nedwill saw the patient in the country about ten days before her admission to the hospital. Her temperature was then 102° F. The fulness in Douglas's pouch was then not nearly so well marked. On Oct. 27th Dr. Nedwill opened the abdomen and found the right tube to be distended and ruptured. The blood-clot had passed over the middle line in front to the broad ligament on the opposite side and down into Douglas's pouch. There was quite a quart of clot turned out. The tube and broad ligament were ligatured and removed. On the left side

there was a small ovarian cyst of about the size of an orange and it was removed. Although Dr. Nedwill occupied some time in sponging out the pelvis he thought that it was prudent in this case to pass in a drainage-tube deep down into Douglas's pouch. On Oct. 28th the patient was very comfortable and the temperature was normal. The drainage-tube was removed. Until Nov. 2nd there was no bad symptom. The temperature was normal on this date. On the 3rd she complained of pain over the right side. The temperature, which had risen to 100·4° on the previous evening, became normal in the morning. The bowels were well opened. The wound had completely healed except where the drainage-tube was inserted. A considerable quantity of sanguineous pus was discharged through this opening. On the 8th the pus was perfectly sweet and was still escaping from the drainage-tube opening. On the 20th the opening had nearly closed; there was no abdominal swelling. On Dec. 1st the patient was well and was discharged from the hospital.

CASE 6. *Hydatid tumour of the brain*.—A girl, aged seventeen years, was admitted to the hospital on Dec. 3rd, 1896. There was no history of mental disease or neurosis in the patient's family. She had always been in good general health, but was inclined to be hysterical. There had been some obstruction to her left nostril for about six years. She did not look robust but she was well nourished. She was quiet and collected in manner and answered questions readily and with intelligence. Eight months before admission she fell from a pony. She appeared to be frightened and excited, but she did not so far as was known sustain any physical injury and was in her usual health on the next day. In the course of the following six weeks she complained of numb sensations in the left hand and sometimes of cramp, the fingers closing on the palm. Little notice was taken of these symptoms at first, but afterwards more attention was paid to them. The paralysis in the arm became almost complete about six months before admission. Two months later weakness of the leg on the same side was observed, the ankle being affected. She was, however, able to get about. She was attended for those symptoms, which were put down to hysteria. The patient herself said that about a year before admission—at any rate, before the accident, which appears to have been a slight one—the right side of the face was drawn up. This was attributed to the faulty position of one of her teeth and was thought to be of no moment. For the last five months she had been subject to attacks resembling epilepsy. Usually the attacks began with a numb sensation in the left fingers which flexed and extended on one occasion. Subsequently the third finger was the first affected. The first three or four attacks were followed by loss of consciousness, but in later attacks consciousness had been retained. Her sight had been good, but about two months before admission she began to see things double. This had interfered with any sustained effort. She was subject to bilious attacks with vomiting and was constipated. She had shown no symptoms of hysteria since her admission to the hospital. The respiratory, circulatory, and digestive systems were normal. There was no evidence of depressed bone in the skull. There was paresis of the left facial muscles, but no ptosis was present. The pupils were equal; the reaction to light and accommodation was normal. The tongue was protruded straight. The pulse was normal. Ophthalmoscopic examination showed that there was double optic neuritis, the neuritis being intense in the right eye. Minute hæmorrhages were observed in both retinæ. She had diplopia, seeing objects multiplied; there was single vision with the left eye, but objects were multiplied with the right eye. The corneal surface was regular. There was very considerable loss of power of the left arm with slight wasting. There did not appear to be any diminution of tactile sensation, but there was considerable analgesia. The muscles reacted readily to the faradaic current; there was paresis of the leg of the same side, the peroneal muscles being chiefly affected. The knee-jerk was increased and there was well-marked ankle clonus. The urine was acid and contained no albumin or sugar. The day after her admission to hospital the patient had an attack resembling epilepsy, consciousness being retained. The attack occurred in the early morning and details were not observed. The patient got up daily and seemed to be in good spirits. On the 13th, while Dr. Walter Fox, the house surgeon, was testing the left leg gently for ankle clonus, she suddenly cried and said that a fit was coming on. She looked pale and seemed to be a good deal frightened. The left wrist was first seen to be in extreme flexion, no separate movement of the fingers being noticed. The forearm was flexed on the arm, the arm commenced to jerk and the left leg was violently drawn in flexion. The spasm of the arm extended apparently to the whole of the side and then to the right arm till the whole body was involved. The eyelids were rapidly opened and shut, the pupils were somewhat dilated but equal, the pulse was rapid, the patient retained consciousness throughout, and could speak. She complained of no pain, but appeared to be much frightened. The attack lasted about thirty seconds, leaving the patient pale but quite collected. Some headache followed about an hour later. She was then menstruating. On the 21st it was noted that during the past week the patient had had two epileptiform attacks, one being attended by complete unconsciousness. On another occasion she was awakened by a violent pain in the right side of the head and became unconscious. There were no convulsions. By Feb. 15th, 1897, the patient's condition under treatment had become more marked, the optic neuritis was more intense and the attacks of headache, vomiting, and Jacksonian epilepsy were more frequent. The left hand and forearm were always moist and seemed to be warmer to the touch; the surface thermometer registered 97°F. On this date (Feb. 15th) she came under the care of Dr. Nedwill. He trephined over the motor area of the right side and came down upon a hydatid cyst. The cyst was emptied of its contents and washed out with boric solution. It held just 4 oz. of this fluid and was quite 4 in. deep. Dr. Nedwill then dried its internal surface by mopping it with sponges and attempted to close it with a continuous fine silk suture, but its cavity quickly collapsed, and he found that, no matter where he inserted a fine needle, hæmorrhage was so free that he had to abandon this procedure. He also found it quite impossible to approximate the edges of the dura mater. A strip of gauze was inserted in the cyst. No bone was replaced. On the 16th the patient slept well; there was no vomiting or collapse. She had a jumping sensation in the left hand. She could move the left arm, flex the elbow, and raise the arm to the shoulder. The gauze was removed and the edges of the scalp were brought together by silkworm-gut sutures. On the 17th the temperature had been normal since the operation and the pulse had been quiet. There was still improvement in the power of the arm. There was a good deal of leakage (blood serum) on the dressing. On the 18th the face was swollen. The temperature was 100°. She had a slight twitching on the left side of the face and arm. On the 22nd there was still a large quantity of cerebral fluid coming from the wound. The patient expressed herself as feeling quite well. On the 23rd the vision of the left eye equalled $\frac{6}{9}$ and the patient could read No. 10 Jaeger; with the right eye she saw the board only. On March 4th the general condition had much improved. She had no headache, vomiting, or fits; in fact, she felt as well as ever she did. The motor symptoms still continued. There was a swelling of about the size of a small orange over the seat of the operation. For some days previously to the 12th a chocolate-coloured discharge had issued from the top of the wound. On the latter date the swelling was increasing and the scar was becoming thin under pressure. On the previous night the patient had twitching in the left leg and right arm, otherwise she was as well as possible. On the 14th the swelling was cut down upon and a quantity of brain substance was discharged. On the 21st the hernia was slightly larger. A small piece of brain substance was protruding through the wound, otherwise the patient was well. Her leg was much stronger and she could walk with greater freedom; the arm was also stronger, but she could not flex her fingers. Her eyesight was not so good; she said that she could not see where she was going. With the left eye she saw only the board and the same with the right (not No. 10 Jaeger). On the 28th ophthalmoscopic examination revealed that the post-neuritic changes in the retinæ were very marked. In the right fundus the swelling of the disc had largely disappeared. The retinal changes in the central area were characterised by white spots with deposits of pigment. The same condition was present in the left fundus but to a greater extent, not, however, so much over the central area. She was discharged from the hospital on April 5th. On May 16th the patient showed herself at the hospital. The cerebral hernia had entirely disappeared. The slight leakage from the scar had stopped. The pulsation over the seat of the operation was little, but

the trephine opening could be distinctly felt. The patient had not had any attacks of headache, sickness, or convulsions. The paralysis of the arm had improved considerably. She could now grasp firmly, whereas when she left the hospital no attempt could be made to flex the fingers. She could flex and extend the elbow and the muscles were much larger and firmer; the same improvement had taken place in the leg; the gait was perfect and it was impossible to detect which had been the affected side. With regard to vision she could not see the test board and could only perceive fingers held at a distance of a few feet from her face. Ophthalmic examination showed the disc to be white and the atrophic vessels small. The appearance previously noted in the retina was not now so marked, but there were still numerous white round spots all over the retina, although more marked in the central region. Her temperature, it may be remarked, both before and after the operation, was normal except on one occasion when it went up to 100. On Sept. 1st the patient again presented herself at the hospital. She was in much the same condition as she was at the time of the last report. There was now spastic contraction of the flexors. It was of course to be regretted that she had not sooner been trephined.

Remarks by Dr. NEDWILL.—I am much indebted to Dr. Walter Fox and his assistant, Mr. Edward Gane, for the trouble they have taken in preparing these notes for me. Dr. Fox made all the ophthalmic examinations. Indeed, the success of the cases reported has been largely due to the great care the patients received from the resident staff in the after treatment.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Urethral and Vesical Calculi.—Cyst of the Urachus.

A MEETING of this society was held on May 24th, Mr. BRYANT, the President, being in the chair.

Mr. LYNN THOMAS (Cardiff) exhibited Urinary Calculi removed from three cases. 1. Nine urethral calculi removed through the perineum of a man. There was a very tight annular stricture behind which the urethra was dilated, and in this dilated sac nine phosphatic calculi had formed. Their total weight was 230 gr. 2. A vesical calculus weighing 6 oz. 6 dr. The stone was too large for removal through the perineal incision and was removed by a suprapubic incision, the extraction being aided by the stone being pushed upwards by the finger introduced through the perineum. The stone was formed of alternate layers of oxalate of lime and uric acid. 3. A vesical calculus weighing 7 oz., also removed through a suprapubic incision. On section it showed a mixed formation. There was an outer layer of oxalate of lime, then one of mixed uric acid and oxalate of lime, then a layer of phosphates, and a nucleus of uric acid and urates. All the cases did well after operation.—The PRESIDENT remarked on the interest of the specimens and congratulated Mr. Thomas on his results.

Mr. ALBAN DORAN read a paper on a case of Cyst of the Urachus, with notes on Urachal and so-called "Allantoic Cysts." The patient was a woman, aged fifty-nine years. During an attack of abdominal pain a cystic tumour of considerable size was detected. The uterus moved separately behind the cyst, which occupied the middle line of the abdomen between the umbilicus and pubes, bulging towards the left. The cyst lay in front of the peritoneum; inferiorly there was another cyst or loculus lying immediately in front of the bladder. A pint or more of dirty brown slightly glairy fluid containing shreds of lymph was found inside the cyst the wall of which was largely made up of plain muscular fibre. After free incision along its whole length the cyst was packed with iodoform gauze. The patient made a good recovery and the cyst shrank to very small dimensions. Mr. Doran noted that Luschka and Wutz showed many years since that the urachal canal was patulous to a certain extent in most human subjects and that minute cystic dilatations were frequent. Urachal fistula was a well-known complaint, sometimes associated with suppuration of part of the canal. Much had been written, especially in Germany and America, on urachal cysts, but the term had been applied too freely to various tumours and collections of fluid closely related to the abdominal walls below the umbilicus. Cases reported by Lawson Tait, George Morgan (Brighton), Ill (Newark, U.S.A.), and Douglas (Nashville, U.S.A.) were quoted by Mr. Doran and compared with his own case; they appeared to be genuine examples of urachal cyst. A remarkable series of very large cysts described by Lawson Tait and Byron Robinson was also referred to. Tait attributed them to arrested development at the stage of embryonic life when the allantois was growing out of the peritoneal cavity. He taught that instead of contracting into the umbilical vesicle the allantois became included in the abdomen; then it served as peritoneum to the pelvic and lower abdominal viscera and sometimes filled with fluid, forming an "allantoic" or big urachal cyst. Tait and Byron Robinson, however, openly admitted that their explanation of the development of these cysts was purely theoretical and had never been confirmed by a post-mortem examination, dissection, or frozen section. Wutz, a few years before Tait's cases were published, showed that older reports of very large "urachal cysts" were faulty. Cases reported by Hoffmann, Heinecke, Roser, and Wolff seemed to Wutz to be more than doubtful. Most of them were probably old encysted dropsies. In Tait's series tuberculous disease of the peritoneum was diagnosed in several instances. Byron Robinson's description of the supposed allantoic membrane which replaced, according to Tait's theory, the peritoneum was compared with notes of the appearances of the parietal and pelvic peritoneum noted by Mr. Doran, Cone (Baltimore), and others in chronic tuberculous peritonitis, with or without encysted dropsy. The theory failed to explain how the bladder, a part of the allantois, seemed to be perfectly normal in Tait's cases, whilst the rest of the allantois underwent at an early stage of development such extreme modifications. In short, Tait's cases, though of high interest and deserving of further consideration, were not certainly of allantoic origin. In conclusion the surgery of true urachal cysts was considered. When such a cyst could be dissected out the peritoneum detached from behind it should be trimmed away as it was apt to slough. Frequently the cyst could not be enucleated from the parietes and the peritoneum and required to be freely incised and drained. In all cases the operator must carefully inspect the relations of the upper boundaries of the cyst to the peritoneum and abdominal viscera. He must likewise be sure that he had determined the position of the bladder below. Its cavity might communicate with the cyst, then the communication must be closed according to the principles of plastic surgery. Every case should be watched as the bladder might give way after the operation through the forcing open of the vesical orifice of the urachus or through yielding of its walls, which had become damaged during operative manipulations, or possibly by the pressure of the drainage-tube.—The PRESIDENT said that the paper had recalled to him two cases which he had met with some years ago whose nature then puzzled him but which he now had no doubt were cases of urachal cyst. The first was that of a woman on whom he operated for a supposed ovarian cyst. In making the incision through the abdominal wall he came on a cyst containing clear serous fluid. On examination this was found to be in front of the peritoneum. Below it was closely attached to the bladder and was separated with considerable difficulty, but ultimately the whole cyst was removed. The wall of the cyst was remarkably thick and fibrous. The second case was that of a man, thirty years of age, who was admitted to Guy's Hospital suffering from severe abdominal pain, high temperature, and a swelling reaching from the umbilicus to the pubes. There was an external abnormality in the shape of slight epispadias. The patient said that there had been a lump of "the size of a small cocoanut" just below the umbilicus for years, but that there had been no pain till shortly before admission. The urine drawn off from the bladder was normal. An incision was made into the cyst and a large quantity of exceedingly foul-smelling matter escaped, but there was no definite urinous odour. The cyst was packed with lint which had been dipped in terebene oil. The cyst contracted up and at about the fourth dressing it was noticed that urine escaped through the wound from time to time. This was verified on several subsequent occasions. The cyst ultimately closed and the man recovered. At the time he thought that he was dealing

with a peri-vesical abscess, but after hearing Mr. Doran's paper he felt certain that this was a urachal cyst.—Mr. DORAN, in reply, said that he was much interested in the cases which had been related by the President. With regard to the one which had been dissected out he mentioned that there was one recorded by Rotter in which there was a cyst above the bladder and on cystoscopic examination a small growth of villous cancer was seen at the fundus. On operation the cyst was found to be a distended urachus. The villous growth had no doubt closed the orifice into the bladder. In the cases mentioned by Mr. Bryant there must have been forcing of Wutz's valve. Mr. Doran pointed out that other cysts, such as ovarian cysts and encysted collections of fluid due to tuberculous peritonitis, might occur at this point. If these were treated by tapping (a method which Mr. Doran strongly condemned) or even if it were drained the cyst might contract up towards the abdominal wall and still more closely simulate a urachal cyst.

HARVEIAN SOCIETY OF LONDON.

Cancer of the Body of the Uterus.

A MEETING of this society was held on May 12th, the President, Dr. J. F. GOODHART, being in the chair.

Dr. HANDFIELD-JONES read a paper on Cancer of the Body of the Uterus. After referring to other causes of uterine hæmorrhage at and after the menopause he brought forward a series of cases which illustrated the difficulty of diagnosing malignant disease of the body of the uterus at an early stage and asked whether growths which might be considered benign adenomata and which remained stationary for a long period might ultimately take on malignant degeneration and rapidly destroy the patient. Some authors had considered all such growths as malignant from the first, but the point was clinically of importance with regard to the possibility of destroying such degenerations at an early stage without resorting to extirpation of the whole womb. The value of uterine scrapings obtained by curettage was discussed and cases were quoted to show the unreliability of such examinations in arriving at a definite diagnosis. Experience went to show that clinical signs and symptoms were of more value in estimating the gravity of the disease and the need for operative measures than any microscopical evidence, though it was allowed that the latter was of value as a confirmatory test. Cases were quoted in support of the view that cancer of the body of the uterus was much less malignant than cancer of the cervix, and evidence was given to show that malignant disease of the body of the womb might run a very long course before producing a fatal termination. Increased experience went to show that cancer of the body of the uterus was not so especially limited to nulliparous women, but occurred with almost equal frequency in those who had borne many children. In conclusion the "early" signs which justified resort to vaginal hysterectomy were reviewed and special stress was laid on rapid increase in the size of the uterus.

The PRESIDENT said that microscopical examination, although sometimes useful in the detection of malignancy, was very unreliable. More valuable evidence was afforded by digital examination and by the clinical aspects of the case. A growth at the time of the menopause was far more likely to be malignant than simple. He was convinced that simple growths might eventually become cancerous. On the other hand, the growth of a cancer was sometimes delayed for months or even for years. In the case of hepatic cancer the growth might become quiescent or even shrivel up and practically disappear. It was therefore difficult to decide whether extirpation of the uterus should be the rule of practice as soon as malignancy was discovered. Much depended on the mortality which attended vaginal hysterectomy, and on this point he asked Dr. Handfield-Jones for further information.

Dr. GOW considered that the microscopical examination of intra-uterine growths was often unsatisfactory and that the evidence of malignancy or non-malignancy obtained by this method should not be allowed to weigh against the results of clinical examination. If a soft, well-defined growth was found inside the uterus of a woman who had passed the menopause and was suffering from hæmorrhage it was a safe rule to consider it malignant and to act accordingly. In some cases where the patient lived many years after malignant disease of the body of the uterus had been diagnosed it was open to doubt whether the diagnosis was correct.

Dr. AMAND ROUTH emphasised the importance of looking upon metrorrhagia at the menopause as a very serious symptom, requiring investigation to determine its origin. He considered the microscopical examination of scrapings from the uterus to be unreliable, owing to the fact that surface scrapings might be benign, yet the deeper parts might be infiltrated with a malignant form of the same growth. He instanced cases of papilloma and adenoma. He thought the finger *in utero* a better guide in most cases. He advocated the removal of any uterus after the menopause where after curetting recurrence of metrorrhagia occurred with a definite progressive enlargement of the body of the uterus, and he would do this even if surface scrapings gave a negative result. Ordinary senile or fungous endometritis did not cause progressive enlargement of the uterus, though it might in a few cases recur and be cured by a second curetting.

Mr. PARKER YOUNG thought that at present too much reliance must not be placed on the microscope, as he had found in undoubted malignant disease, both of the uterus and the breast, that negative results were obtained, and one ought, therefore, to be careful in pronouncing an opinion that the case was not malignant when the examination by the microscope failed to detect it. In listening to the paper he had not heard mention of examination *per rectum*, which often helped materially in diagnosis, as did the peculiar offensive odour of the discharge. As regarded the length of time which patients the subjects of malignant disease might live, one case pronounced as such by leading gynæcologists had survived over ten years without any operative interference.

Mr. C. B. KEETLEY asked whether oöphorectomy had been practised in cases of uterine cancer.

After some remarks by Mr. JACKSON CLARKE, Dr. HANDFIELD-JONES replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Action of certain Drugs and Mineral Waters on the Secretion and Composition of the Bile.—Effect of Exercise on the Hæmoglobin.—Leontiasis Ossea.—Gangrenous Appendicitis with Peritonitis.—Exhibition of Cases and Specimens.

A MEETING of this society was held on May 6th, Mr. C. J. WRIGHT, Vice-President, being in the chair.

Dr. BAIN (Harrogate) read an interesting paper on the Action of certain Drugs and Mineral Waters on the Secretion and Composition of the Bile.

Dr. EDGECOMBE (Harrogate) read a paper on the Effect of Exercise on the Hæmoglobin with reference to the Value of Rest in the Treatment of Anæmia, embodying the results of a long series of observations which he had made. After referring to the daily variations in hæmoglobin, corpuscles, and in the worth of the corpuscles that normally occur in healthy subjects, he showed that these variations are reversed in subjects who work during the day and rest during the night, the extent of the variation being roughly proportionate to the amount of exercise taken. The effect of active exercise was to cause a fall in worth or loss of hæmoglobin. Examining a large number of exercise days and comparing them with no-exercise days he showed that the normal day fall and night rise in worth of the corpuscle were considerably greater after exercise than after no exercise, the rise being in excess of the fall, thus proving that exercise causes a slight over-production of hæmoglobin. The average level of the worth was higher during a period of free exercise than during a sedentary period. Passive exercise (massage) caused a diminution in the volume of the blood without any change in worth of corpuscle. The effect of rest in bed was to lessen the amount of the day fall in worth. He summarised his conclusions as follows: (1) there is a normal day fall and night rise in the worth of the corpuscle representing a destruction and regeneration of hæmoglobin; (2) active exercise primarily increases the amount of destruction and secondarily stimulates a more than corresponding reproduction; (3) passive exercise diminishes the volume of the blood without affecting the worth; and (4) rest reduces the extent of the day fall in worth, representing a diminished destruction of hæmoglobin.

He concluded by pointing out the bearing of these facts on the treatment of anæmia, adding that they provide a physiological foundation for the well-known value of rest in bed in the treatment of that affection.

Dr. CHURTON showed a case of Leontiasis Ossea in a girl, aged nine years. The child weighed 3st. 5lb. The parietal region was much enlarged and the bones were thick and firm; the occipital ridge was thick. The nasal bones were level with the enlarged superior maxillæ, so that no bridge seemed to exist. The temporal and malar bones were thickened. The lower jaw, although much enlarged, was small in comparison with the upper. The chest was not deformed but the ends of the ribs were markedly enlarged at the anterior ends. The spine was normal. The lower ends of the radii and ulnæ resembled the appearances seen in rickets. The pelvis was perhaps thickened. The femora were short and curved outwards and the tibiæ were curved forwards. The external and internal malleoli were thick and elongated. The patient was the ninth child in a healthy family and was well and strong up to seven years of age. There was no diminution of intelligence. During sleep perspiration was rather profuse about the head.

Mr. LITTLEWOOD showed a case of Gangrenous Appendicitis with Peritonitis. The patient was a man, aged twenty-two years, on whom he had operated on April 2nd, 1898. The attack commenced six days previously. At the time of operation the temperature was 99° F. and the pulse was 80. The abdomen was opened in the middle line. The small intestines were distended and inflamed, with patches of purulent lymph on the surface. The right rectus was divided. The appendix was found to be quite gangrenous and lying in a collection of pus on the right surface of the mesentery of the small intestine. The appendix was removed and the peritoneum was wiped out with gauze and gauze drainage employed. The pulse rose to 120 after the operation and on the evening of the next day was 148. On the fifth day the pulse was 100. The bowels were well opened in about twenty-four hours with large doses of Rochelle salts and enemata. The patient made a good recovery.

The following cases, pathological specimens, &c., were exhibited:—

Dr. CHURTON: A case of Paræsthesia of the Seventh and Eighth Cervical and First Dorsal Nerves, caused by localised Syphilitic Pachymeningitis.

Dr. LIDDELL (Harrogate): (*a*) Two cases of Ichthyosis; and (*b*) a case of Raynaud's Disease.

Dr. HELLIER: Thrombosis of the Broad Ligament Veins from a Puerperal case (with temperature chart).

Mr. PRIDGIN TEALE: "Carter's Suture Case," for use in fracture of the jaw, which he has designed and presented to the Leeds Infirmary.

Dr. ADOLPH BRONNER (Bradford): (*a*) Case of Osteo-Sarcoma of the Orbit; and (*b*) case of Transplantation for Traumatic Defect of both Eyelids.

Dr. TREVELYAN: (*a*) A case of Recurrent Syphilitic Hemiplegia with Anomalous and Partial Recovery from the Second Attack; (*b*) a case of Secondary Spastic Paraplegia, Recovering; (*c*) an Unusual Case of Paralysis of one Arm; (*d*) a case of Erythro-Melalgia with Trophic Disturbance; (*e*) Cultures from a case of Acute and Complicated Lumbar Myelitis; (*f*) a specimen of Cerebral Hæmorrhage; and (*g*) a case of Deep Jaundice with considerable Glycosuria.

Dr. TREVELYAN and Mr. LITTLEWOOD: An unusual specimen of Laryngeal Tuberculosis, with microscope preparations.

Mr. LAWFORD KNAGGS and Dr. TREVELYAN: A case of Traumatic Division of the Sciatic Nerve six months ago, with immediate suture.

Mr. LAWFORD KNAGGS: (*a*) Colectomy nine months ago—patient and specimen; and (*b*) Erasion of Ankle by Clutton's Method.

Mr. HALL (Bradford): Columnar Carcinoma of the Ovary.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Anterior Colporrhaphy.—Toxæmia in Pregnancy.—Cæsarean Section.—Hysterectomy.

A MEETING of this society was held on May 11th, Dr. MILNE MURRAY, Vice-President, being in the chair.

The following specimens were exhibited:—

Dr. HALLIDAY CROOM: (1) Myoma of the Ovary; (2) a Dermoid Ovarian Tumour; (3) Fibroid removed by Hysterectomy; and (4) a Fibroid removed by Myomectomy, part having to be cut away before the ovaries could be reached for their removal.

Dr. BREWIS: A Four Months Pregnant Uterus with several small fibroids and one large cystic fibromyoma attached; owing to the rapid growth of the latter the whole was removed by hysterectomy.

Dr. JARDINE (Glasgow): (1) Drawing of a Curious Central Tear of the Perineum; and (2) Two Uteri from cases of Cæsarean Section.

Dr. R. C. BUIST (Dundee): Uterus with a Malignant Adenoma of the Fundus removed from a patient where the symptoms commenced eighteen months after the menopause.

Dr. HAULTAIN: Tubal Gestation evidently at the end of the second month and removed for internal hæmorrhage; there was no rupture but the blood was seen escaping from the fimbriated extremity.

Dr. HAIG FERGUSON: Two specimens of Tubal Gestation removed at one operation from the same patient; the one was an intra-ligamentous sac and the other a lithopædion.

Dr. R. C. BUIST read a paper on Recent Modifications of Anterior Colporrhaphy. Cases of prolapse may be divided into two large groups—(1) those with an initial retroversion or retroflexion, and (2) those with initial weakness of the pelvic floor and cystocele. Cystocele implies the existence of weakness, not only of the pelvic floor, but also of the muscular wall of the bladder. The normal bladder can empty itself in virtue of its intrinsic contraction in whatever position the body may be. In cystocele this power is lost and unless the patient adopts special means the bladder is never entirely emptied and the bladder wall is thus never fully contracted. A vicious circle is thus produced, impairment of the muscle is soon induced, and this again increases the difficulty of evacuation. From this point of view the obliteration of the cystocele is an important factor in the success of any treatment of prolapse. The fact that scar tissue is weak tissue is one of the most important elements in the failure of operations for prolapse of the female genital organs, and many ways have been devised to get rid of this weakness and to ensure that the scar or line of greatest weakness should not coincide with the line of greatest strain. After referring to the methods of different operators it was noted that nothing was done directly to correct the dip of cystocele. Dr. Buist described a plan he had carried out in operating on a case of cystocele persisting after the operation of total extirpation of a uterus and cystic ovaries. He made on the anterior wall of the vagina a mesial incision extending from the urethra to the fundus of the vagina, dissecting on each side between the vagina and the bladder with the handle of the knife. He then stitched the loose bladder wall together with chromic gut, passing the stitches through the muscular wall only and puckering the loose portion together. The anterior vaginal wall was then shortened by bringing the two ends of the longitudinal incision together so that it became transverse and stitching it up in that position. As the vulvar cleft was rather long the knife was carried round the posterior part of the aperture, splitting as in Tait's operation. The result is up to the present completely satisfactory.—Professor SIMPSON stated that the operations for this condition, though giving good results at first, were unsatisfactory owing to the cicatricial tissue giving way. Dr. Buist's proposal was interesting and ingenious and well worth a trial.—Dr. HAULTAIN had leanings towards ventrofixation as the operation for relief of these conditions, as the results were very satisfactory and there was little or no risk attached to it.—Dr. BARBOUR, Dr. BALLANTYNE, and Dr. MILNE MURRAY joined in the discussion and Dr. BUIST replied.

Dr. KYNOCH (Dundee) read a paper on Toxæmia in Pregnancy, with illustrative cases. By toxæmia in pregnancy is generally understood that condition occurring in the pregnant state as the result of the presence in excess of toxic material; as far as is known the character of the poison is of the nature of alkaloids. The excretion of waste material is in large part effected through the kidneys and this may account for the albuminuria of pregnancy rather than mechanical pressure or reflex spasm. Clifford Allbutt finds evidence for the presence of a circulating toxin in pregnancy from the fact that healthy urine contains toxic material. The nature of the poison is unknown. Bouchard found that it was not urea. Many obstetricians regard the convulsions as arising from the action on the nerve centres of a poison which is the result of tissue metabolism elaborated partly by the mother and partly by the fœtus. Bacteriological researches of different

investigators all point to the same conclusion. Lindermann has recorded a case of fatal vomiting where he found neuritis in several nerves with fatty degeneration of the liver and kidneys in both mother and fœtus; the spleen was also enlarged, differing from the atrophy which is found when death has been due to inanition. He accordingly believes the cause of the vomiting in this case to have been an auto-intoxication. Salivation in early pregnancy has also been thought due to excess of toxin present in normal urine. Toxins absorbed from the bowel may be rendered harmless by the protective influence of the liver, but if disease of the liver be present or an excess of toxins be absorbed then symptoms of poisoning are produced. Dr. Kynoch then gave details of three cases.—Professor SIMPSON, Dr. CONNEL, Dr. CALDER, Dr. HAULTAIN, Dr. BUIST, and others took part in the discussion.

Dr. JARDINE (Glasgow) read notes of four cases of Cæsarean Section. This operation is now displacing craniotomy to a certain extent, but that it will ultimately take the place of the latter is not to be expected. The first case was that of a primipara; labour had lasted for some time; the os was of the size of half-a-crown with the membranes unruptured. The pelvis was rickety. The operation was carried out in the usual way. The bleeding from the uterus was controlled by Comerni's method of firmly pressing a pessary down in it, thus enabling the operator to dissect slowly down till the membranes bulge into the wound, which can then be enlarged to the full size of the pessary with practically no loss of blood. The pessary is quickly removed and the incision is enlarged sufficiently to extract the child. An arm presented but the feet were grasped and the child was quickly extracted. The child was alive but, like all these children, required resuscitation. The uterus was firmly grasped by an assistant and the placenta was quickly expelled. From 18 to 20 No. 10 silk sutures were put into the uterus, including the muscular and serous coats, also a few superficial catgut sutures. The Fallopian tubes were then tied in two places and divided between them, so as to effectively sterilise the patient. The abdomen was closed in the usual way. Convalescence was uneventful. The infant had a hæmorrhagic vaginal discharge when five days old. The pelvis had a diagonal conjugate of $3\frac{5}{16}$ in.; the conjugata vera would be about $2\frac{1}{2}$ in. Eight months after operation a small abscess formed to the left of the cicatrix and is still discharging. As the uterus is free and atrophied the discharge is probably coming from the seat of the ligatures on the left tube, in which region there is some thickening. Menstruation has occurred every three weeks since the operation. The second case was that of a woman very deformed with a diagonal conjugate of $2\frac{3}{4}$ in. and a true conjugate of less than 2 in. The patient recovered well; she has not menstruated since the operation. Details were then given of a third case which developed symptoms of septicæmia and the patient died four days after the operation. Post mortem there was distinct evidence of peritonitis. The fourth case was that of a woman pregnant with her fourth child; the three previous had required craniotomy. The conjugata vera was estimated at $2\frac{1}{2}$ in. At the operation the os was nearly fully dilated and the membranes had ruptured. In this case the incision was carried well up to the fundus; the child was resuscitated. On the second day the urine was found to be albuminous and to contain tube casts. She died on the seventh day, evidently from nephritis. It was thought she might have contracted a chill just before the operation. Post mortem the abdominal and uterine wounds were found to be healthy; there was no peritonitis.

Dr. JARDINE also read a short note on a Curious Central Tear of the Perineum.

Dr. N. T. BREWIS gave notes of a case of Total Hysterectomy for large Fibrocystic Tumour of the Uterus. The patient when seen had not menstruated for four months and had a rapidly growing tumour in the abdomen. This was found on operation to be a large fibrocystic tumour weighing 10 lb. and attached to the uterus by a pedicle. The abdominal wound was closed without drainage. The patient made an excellent recovery.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Adeno-Carcinoma of the Mamma.—Addison's Disease.

A MEETING of this section was held on May 6th, Dr. J. M. PURSER, the President, being in the chair.

The SECRETARY, Dr. McWeeney (for Mr. WHEELER), described a specimen of Adeno-Carcinoma of the Mamma and demonstrated the slides, which presented the typical microscopic appearances of this condition—a plexus of glandular tubules, most irregular in shape, occasionally filled up with epithelium, elsewhere cystic, and presenting small papillomatous ingrowths. In places the basement membrane had been broken through and irregular masses of epithelium were lying free in the connective tissue. The cells were mostly high-columnar, but in some groups were nearly cubical and presented typical examples of the conditions described by Hansemann as anaplasia and hyperchromatosis. To the naked eye the tumour resembled a lymphatic gland, being soft, white, egg-shaped, and distinctly encapsuled. The microscope showed that in one spot the tubular structure had broken through the capsule and had just begun to invade the adipose tissue outside. The tumour had been removed from a woman, aged sixty-seven years, and had been noticed a year prior to operation. — Dr. E. H. BENNETT said the case reminded him of one which occurred in his practice three years ago. The tumour in this case was freely moveable, non-adherent to the skin or the tissues of the gland. The patient was thirty-five years of age and was in the third month of pregnancy, but he removed the tumour as it was growing rapidly, though believed to be benign. It was encapsuled and shelled out quite easily. The patient recovered in six days. Subsequent examination of the tumour proved it to be a most malignant adenomatous carcinoma—rather a carcinoma than an adenoma. In less than two months it recurred and he removed the breast and tumour and glands in the neighbourhood without meeting any infected tissue in the glands. The operation was severe and was almost immediately followed by abortion. Recovery ensued and at present there is no sign of recurrence. — Dr. MCWEENEY, in reply, said that Dr. Bennett's case interested him much. The condition of an undoubtedly encapsuled tumour proving to be malignant was of considerable clinical interest.

Dr. A. R. PARSONS described three cases of Addison's Disease.—Dr. CRAIG said that he thought the second case the only one of the three which seemed to agree with all the symptoms which go to form a picture of Addison's disease.—Dr. MCWEENEY expressed surprise at the diagnosis in the first case. In the only necropsy he had made in Addison's disease—a case under the care of his senior colleague, Sir C. Nixon—it was difficult to find any adrenals at all. They were reduced to yellowish masses no thicker than paper, forming hardly perceptible thickenings on the capsule covering the upper and inner aspects of each kidney. Microscopic examination showed this to consist of somewhat pigmented fibrous tissue containing a number of very atrophic-looking ganglion cells. There were several parallel lines of these, probably about 40 or 50 cells in all; they had lost their processes and had become extensively pigmented and rounded in outline, and it was only from their large size and the peculiar appearance of their nucleus and the fact that some of them had kept some stumps of their processes that it was possible to make the diagnosis that they were ganglionic in origin.

BRISTOL MEDICO-CHIRURGICAL SOCIETY — The eighth meeting of the session was held on May 11th in the Medical Library of University College, Dr. J. E. Shaw being in the chair.—Dr. B. J. Baron showed a patient with Congenital Syphilis of the Throat and Nose.—Dr. J. O. Symes showed microscopic specimens of Trichomycosis Nodosa (Lepothrix).—Dr. W. H. Newnham showed a specimen of Dermoid Cyst. Dr. Aust Lawrence commented on the specimen.—Dr. W. H. Newnham read a paper on Twelve Abdominal Sections. Mr. Morton. Dr. Aust Lawrence, Dr. Waldo, Mr. Carwardine, and Dr. E. H. Stack spoke on the subject.—Mr. W. R. Ackland read a paper on Some Secondary Effects of Dental Irritation. Mr. Harsant, Mr. Ewens, Dr. Cave, and Dr. Aust Lawrence discussed the paper.—Professor Fawcett showed numerous anatomical specimens recently added to the school museum; he also showed various microscopic specimens of the Minute Anatomy of the Brain, and on this subject he spoke at length and illustrated his remarks by many diagrams and by a large number of beautiful sections which he threw directly on the screen by means of the oxy-hydrogen light.—Professor Fawcett read a paper on the Surgical Anatomy of the Frontal Sinuses and exhibited a large number of skulls to illustrate his paper.

Reviews and Notices of Books.

A Student's Textbook of Zoology. By ADAM SEDGWICK, M.A., F.R.S. Vol. I. London: Swan Sonnenschein and Co. 1898. Price 18*s*.

THE work of Professor Adam Sedgwick is so well known to teachers and students of zoology in this country in his English edition of Claus' Lehrbuch that the present work will be sure to attract considerable interest. It is called a Student's Textbook but we cannot help thinking that a teacher's reference book would more aptly describe it. This is owing to the fact that the system of fully describing types of the chief divisions of the animal kingdom has been intentionally set aside in order to gain room for the notice of a greater number of animals' names. The result is that the book is full of information, indeed for its size it probably contains a larger number of absolute facts than any other work of its kind, but in our opinion the matter is too condensed to be easily assimilated by the student. There are no introductory chapters on the general structure of animals or on the principles of classification but the work opens with a definition of the Protozoa followed by a table showing their classification. The various classes and subclasses are next dealt with and the orders and families noticed with considerable condensation. To each family a singularly complete list of genera is added and the authority for each genus is placed in brackets after its name. We may notice in passing that Hæmatoococcus and the Mycetozoa are included among the Protozoa. In this way the animal kingdom from the Protozoa to the Chætognatha is described, the Arthropoda, Echinodermata and Chordata being reserved for another volume which, the author states, is in preparation. This second volume will, if there is room, include a part dealing generally with the facts and principles of zoology. The references to current literature are singularly full and are brought well up to date; they are placed, not in a bibliography at the end of the book, but, where they are likely to be most useful, in footnotes after the various orders and families with which they deal. The mass of names with which the book abounds renders a complete index most necessary and the author is to be congratulated on having supplied a very excellent one. The illustrations are numerous and are mostly those with which readers of Claus' book are familiar; they are clear and help the text but are otherwise of little artistic merit. The book is a most valuable contribution to zoological literature and will be of special use to advanced students and teachers as well as to those working at special groups who wish to keep in touch with general zoology. We hope that it may meet with sufficient success to be kept well up to date in the future.

Therapeutics of Infancy and Childhood. By A. JACOBI, M.D. Philadelphia: J. B. Lippincott Company. Second edition. 1898. Price 15*s*.

THE author in this work gives the results of his long experience of the diseases of childhood and the practical information which the book contains will be found very useful by those whose daily practice brings them face to face with sick children. Since the well-being of every child depends so much upon proper feeding and healthy surroundings, the author has done well to devote a large space to those important subjects, diet and hygiene. No attempt is made to give universal rules which shall be applicable to every case, for that is impossible, but the general principles upon which a suitable diet in health and disease must be based are clearly laid down, and when they are well understood the exceptions will be found less difficult to deal with. The importance of water as a therapeutic agent is strongly insisted on. Large quantities of it should be mixed with the infant's food, and the author thinks that many digestive disturbances can be explained by a deficiency of this fluid. Healthy children should also be offered an occasional drink of water, as they sometimes wish for drink when they do not wish to eat, and in many general diseases, such as diarrhœa, fevers, &c., it is very important that water should be plentifully given.

The methods of feeding and nature of the foods best suited to children are considered in detail.

In the chapter on General Therapeutics there will be found general directions for the treatment of different diseases and many useful hints on the administration of medicines are given. The necessity of making a diagnosis before entering upon treatment and the dangers of trusting too much to the practice of "meeting symptoms as they turn up" are pointed out.

The treatment of the different diseases are then considered in detail under the heads of the various systems. The author is a strong believer in the efficacy of drugs when they are skilfully used and he has produced a book which will be a valuable guide to others.

The Elements of Hypnotism. By RALPH HARRY VINCENT. London: Kegan Paul, Trench, Trübner, and Co. The International Scientific Series. 1897. Price 5*s*.

THE author claims for hypnotism that it has now gained a position in the scientific world and therefore approaches the subject from the scientific standpoint.

From time immemorial has existed and been recognised a condition of the mind linked in the superstition of the past with various unknown powers. It has been attributed to the Deity and to the Devil, to a universal fluid, to animal magnetism, and to galvanism. Even animal magnetism and galvanism have now been differentiated, having no more to do with hypnosis than the "aëriform fluid" of John Baptist van Helmont which we now know as gas.

Mesmer seems to have been ignorant of the real nature of his power, confusing it with something absolutely and entirely distinct from hypnotism as we now understand it. He was, as the author remarks, attracted to the question of magnetism, his interest being aroused by certain wonderful "cures" performed by one Father Hehl, a Jesuit, who effected them, so it appeared, by the subtle influence or fluid which was imparted to the patient from steel plates and magnets specially prepared for the purpose. But under all the charlatanism of Mesmer lay the subtle power, as yet not understood—real yet indefinite, potent yet illusive: a something which had influenced humanity in all ages and could influence the lower animals also, and which has dominated the imagination of every old lady when she has religiously swallowed her bread pill. It is the force we now recognise in hypnotic suggestion.

Having passed in review the historical aspect of the question and presented the student with a variety of ideas both with regard to animal magnetism and mesmerism and with regard to the hypnotism of the present day divested of what Dr. Lloyd Tuckey calls "a mass of superincumbent rubbish" the author proceeds to place the investigator on a sound and scientific basis. In a chapter headed "The Physiology of Hypnosis," which the author in his preface to the present edition informs us is entirely new, he considers that the method there suggested is the one most likely to yield results of permanent value. He remarks that in order to obtain an accurate view of the relations of the hypnotic to the normal condition it is necessary to have a clear conception of the following: the nature of nervous action,

of the structure and function of the nervous system, of the interdependence which exists between the various organs of the body and the central nervous mechanism and of the character of this interdependence. In making such a demand as this the author seems to us to be asking a great deal and we doubt if there are many even of the leading physiologists of the day who could claim a clear conception such as he requires.

In the following pages, however, he sets forth a description of the nervous system which is, perhaps, after all, sufficient for his purpose. After tracing the course of an external impression or stimulus to the reflex action in which it results he dwells particularly upon the inhibitory influence exerted by certain portions of the nervous system upon the remainder and arrives at the conclusion, the originality of which possibly lies with Bernheim, that the etiology of hypnosis is largely dependent upon the alterations in the nervous balance of inhibitory impulses. He considers the condition of hypnosis to be the result of an inhibitory influence over the higher psychical activity and that with the conscious function debarred from action the stimulus is expressed in other than conscious terms, the operator being enabled to regulate the course of a given stimulus and determine its reaction.

Although the ideas expressed are merely speculative and the book does not add to our knowledge in the same definite manner as the practical experience of such writers as Kingsbury, Lloyd Tuckey, or Milne Bramwell, or the collection of cases published by J. M. Wood, still it is a welcome contribution to the store of our literature upon the subject.

Schenk's Theory: The Determination of Sex. By Dr. LEOPOLD SCHENK, Professor at the Imperial and Royal University and Director of the Embryological Institute in Vienna. Authorised translation. London: The Werner Company. 1898. Pp. 173. Price 5*s*.

PERHAPS no medical question of the last twelve months has excited so much interest among a considerable section of the public as the newspaper announcement that Dr. Schenk of Vienna had discovered a method of predetermining the sex of children. Under any circumstances such a statement could hardly fail to attract attention and in the present instance additional piquancy was imparted by the suggestion that some noble family or other had been enabled by this discovery to obtain that desideratum, a male heir. Dr. Schenk, who is Professor of Embryology in Vienna University, has now explained his views to the world in a volume of moderate size, an English edition of which is published simultaneously with the German original. After a sketch of various theories of sex production which have been held at different periods both ancient and modern he gives a qualified adhesion to that of cross heredity (*gekreuzte Geschlechtsvererbung*), according to which the offspring tends to be of the opposite sex to that of the more vigorous of the two parents, so that if the mother in her way is of greater procreative capacity than the father in his the offspring will tend to be of the male sex. The nutrition of the mother is, according to Dr. Schenk, the principal factor in bringing about this result. In order that she may have male progeny her food must not only be of a kind calculated to maintain her in health and strength, but she must in addition be able to assimilate it so completely that her urine yields no sugar when submitted to the sensitive phenylhydrazin test. On the other hand, women whose urine contains even minute traces of sugar are more likely to have daughters than sons; but they are able not unfrequently to reverse this tendency if they are willing for some months before conception to exclude carbohydrates from their food as much as possible, confining themselves mainly to nitrogenous and fatty diet. The frivolous-minded will welcome these views as a complete solution of the momentous question, What to do with our girls? but, speaking seriously, the method is not one for universal application and expectant couples will do well not to be over-sanguine. Abstract arguments can serve no useful purpose, while, on the other hand, the theory may be easily tested by the average of a moderate number of cases. Sterility is not touched upon at all—in fact, fecundity is presupposed; and Dr. Schenk expressly states that he is not prepared with any suggestion for creating a tendency towards female births. The book is unpretentiously written without any straining after effect or any lavish use of technical terms or any passages which might offend professional susceptibilities; the author's position in one of the great continental medical schools will be a sufficient inducement to gynæcologists and obstetricians to make themselves acquainted with its contents. The English version follows the German edition as closely as the idioms of the two languages permit.

Sajous' Annual and Analytical Encyclopædia of Practical Medicine. Philadelphia: The F. A. Davis Co. Vol. I. Price 5 dollars.

IT is with some regret that we notice that the invaluable Sajous' Annual will appear no more, at least in its old form. That form was simply a necessity for ourselves as medical journalists, but according to its editor it did not always meet the demands of the general practitioner. Dr. Sajous has therefore conceived the idea of uniting in one volume a text-book of medicine and a reference book. It is arranged alphabetically, and one volume will appear every six months and the whole alphabet will be covered in three years. During this time there will also be issued a monthly supplement containing the very latest extracts from medical journals as additional references. The first volume now before us contains subjects from Abdominal Injuries to Bright's Disease, and they are arranged on the following plan. First is given a description of the disease, its definition, symptoms, etiology, pathology, diagnosis, prognosis, and treatment. These are all printed in large type and are interspersed with quotations in small type from the literature of 1896 and 1897 dealing with the various matters treated. It will thus be seen that though the new form does not quite take the place of the old one in some ways yet in others it does what the old one could not do—i.e., act as a text-book—and we have no doubt that the addition of the monthly Cyclopædia will make the reference matter as complete as was the old five-volume edition. The associate editors number one hundred and come from many European countries as well as from the United States. The book is carefully printed and beautifully illustrated and reflects great credit upon all concerned in its production. It is, of course, impossible in the space and time at our command to adequately review a work of this character, so that we have only attempted to give some idea of its scope. Subscriptions must be taken out for the entire series at $5 per volume—i.e., $30 in all—and this will secure a six-volume reference work with thirty-six monthly supplements of journalistic medical literature.

LIBRARY TABLE.

The X Rays: their Production and Application. By FREDERICK STRANGE KOLLE, M.D. New York: J. S. Ogilvie Publishing Company.—We venture to think that it is time that some limit should be put upon the publication of x ray manuals large numbers of which have been printed since the memorable discovery by Professor Roentgen. We are far from saying that the x ray experimentalist should be without a knowledge of the principles

underlying electrical phenomena. The x rays are, of course, a manifestation of electric energy and the proper place to discuss the subject is in a work or text-book on physics. The present editions of our standard works on physics with a few exceptions do not treat of the x rays, but there is little doubt that these will shortly be brought up to date and that room will be found for a chapter on the x rays in extension of the general subject. As a rule more than one-half of the books on x rays are devoted to pure physics, the practical application of the rays being sufficiently described in a few pages. In the book before us, Part I., consisting of 53 pages, is devoted to the description of electrical phenomena, which would be found in any standard work on electricity. Other 14 pages are devoted to photography — how to print, tone, fix, &c. The chapters on x ray apparatus and the practical application of the x rays in surgery, &c., are distinctly good, but there are plenty of text-books (too many we think) of equal merit in this respect. We repeat that further works on this branch of electrical phenomena are not wanted, and they will be still less needed when new and revised editions of the standard works on physics are issued.

Lehrbuch der Physiologischen Chemie mit Berücksichtigung der Pathologischen Verhältnisse, für Studierende und Aerzte. (*Manual of Physiological Chemistry with Reference to Pathological Conditions, for Students and Physicians.*) Von RICHARD NEUMEISTER, M.D., Ph.D., Professor der Physiologischen Chemie an der Universität Jena. Zweite Auflage. Jena: Gustav Fischer. 1897. Price 17 marks.—This is probably one of the most comprehensive works on the subject, having no exact analogue in the English language. The excellent text-book of Chemical Physiology and Pathology by Dr. Halliburton is the nearest approach to it in regard to the ground which it covers and its practical sections. A remarkable and admirable feature of the work before us is the carefully compiled bibliography which is conveniently distributed throughout the pages in footnotes. Amongst these references we find frequent mention of articles published from time to time in THE LANCET. The index is also exemplary both in regard to authors and subjects. The book is divided into two chapters: I. Nutrition, and II. the Animal Tissues and Fluids. The former chapter is divided into six sections and the latter into nine sections. The largest section in the book is that devoted (fünfzehnter Abschnitt) to the urine, being subdivided into twelve paragraphs. The subject matter has been well brought up to date, as will appear from the processes given for the separation of albumins, of proteoses, &c., and the complete analyses of urine with especial reference to creatinine, glycuronic acid, inosite, &c. To those engaged in physiological research, to pathologists, and to workers in like fields possessing a knowledge of technical German, the book will be most valuable for reference purposes.

Praxis der Harnanalyse. (*The Practice of Urine Analysis.*) Von Professor Dr. LASSAR-COHN. Zweite Auflage. Hamburg und Leipzig: Leopold Voss. 1898. Preis 1 mark.—This is a handy practical *brochure* on the examination of urine presenting just that information to the practitioner which will guide him in diagnosis. We find nothing novel in the methods described. They are in general simple and accurate. No importance appears to be attached to the estimation of uric acid. This may now be done with greater accuracy than hitherto by the ammonium-chloride method, the resulting precipitate of acid ammonium urate being converted into uric acid by the addition of hydrochloric acid. In the concluding pages will be found a short and useful chapter on the analysis of the gastric juices.

Pasteur. By PERCY FRANKLAND, Ph.D., B.Sc., F.R.S., and Mrs. PERCY FRANKLAND. London, Paris, and Melbourne: Cassell and Co., Limited. 1898.—To workers in every field of science there could not be a more interesting biography added to "The Century Science Series" than that of Louis Pasteur. There is a chapter for everyone: the chemist, the pathologist, the physiologist, the bacteriologist, the manufacturer—in a word, all. Dr. Frankland and his wife have given us a delightful and simple sketch of the great man's career in the volume before us. It is not very long since the world mourned the loss of Pasteur, and the interesting details of his life gathered from the full obituary notices in our own columns and elsewhere will still be fresh in mind. The story of Pasteur's great achievements will never pall and Dr. and Mrs. Frankland's book will be often taken from the shelf for reference to its clear and well-written chapters. Though a small volume it contains a remarkably complete outline and all scientific workers will be grateful to its authors and will rightly regard it as a simple but worthy tribute to the great master.

Glass Blowing and Glass Working. By THOMAS BOLAS, F.C.S., F.I.C. London: Dawbarn and Ward, Limited; New York: Truslove and Comba. 1898. Price 2*s.* net.—To the practical chemist some knowledge of glass-blowing is indispensable, and inasmuch as chemistry is a branch of medical science the little book which Mr. Bolas has produced will be read with profit by medical students. Within a space of 212 octavo pages the author has contrived to say all that anyone needs to know about *ars vitraria*, including a historical sketch of the art and a practically complete bibliography. The only omission in this latter portion of the book appears to be "Souffleur à la Lampe et au Chalumeau, par M. Pédroni," published in the Librairie Encyclopédique de Roret, Paris. Among the novelties contained in the book is the description of the blowing of bulbs from solid glass rods—an art which has almost been forgotten—and an account of the manufacture of a new kind of draughtsman's pen, the invention of the author. This pen consists of a reservoir from which issues a capillary tube (the "nib") and the little instrument should prove very useful in applying caustic liquids in surgery. The description of a syringe consisting entirely of glass is interesting and this syringe should prove useful from an aseptic point of view. The book is embellished with a coloured frontispiece illustrating a number of fancy articles for decorative purposes which are well within the scope of an amateur's ability, and practical drawings of all processes are scattered throughout the text. In writing the manual the author has kept in view the words of his preface, "I have aimed at making the present work not only a laboratory, workshop, or household guide to the various phases of glass-working at the blowpipe, but also to some extent technically educational in the real sense of the term, as leading towards an understanding why each particular thing is done and as facilitating that interdrift of method from craft to craft which is so conducive to progress." Altogether the book can be thoroughly recommended and should stimulate many to practise glass-blowing as a useful hobby.

Notes on the New British Pharmacopœia, 1898. London: C. J. Hewlett and Sons.—This well-known firm of druggists have sent us a useful little pamphlet under the above title. It notes in succession the Changes in Nomenclature, the Weights and Measures, Dosage, Additions, Omissions, Important Alterations, New Drugs, Formulæ and Processes. The work should be found very useful to practitioners, for it shows at a glance the alterations in the new Pharmacopœia which will have to be remembered, and the table of important alterations in particular will be found valuable. The conclusion the writers come to is that the new Pharmacopœia

is a decided advance upon its predecessors but that it might be still better. We may add that Messrs. Hewlett offer to send a copy to any medical man who applies for one. Their address is 40, Charlotte-street, E.C.

JOURNALS AND REVIEWS.

Manchester Royal Infirmary Students' Gazette.—The first number of this new periodical appropriately makes its appearance with the opening of the summer session and commences so well that we heartily wish it success. The members of the infirmary staff contribute a number of articles, the most entertaining of which is devoted to the clinical history and probable post-mortem appearances of Sir John Falstaff.

Analytical Records

FROM

THE LANCET LABORATORY.

(1) ZOMÈLA SKIN SOAP; AND (2) UNGUENTUM ZOMÈLA.

(THE ZOMELA CO., LIMITED, ZOMÈLA-BUILDINGS, JOHN BRIGHT-STREET, BIRMINGHAM.)

BOTH preparations were found to be of decided merit. The soap was perfectly neutral, bland, and pleasant to use. On applying the phthalein phenol test for free alkali the result was quite negative. The ointment was found to contain lead in association with a fatty basis of a permanent character, that is, one without any tendency to become rancid.

FEVER FOOD.

BRAND AND CO., MAYFAIR WORKS, SOUTH LAMBETH ROAD, VAUXHALL, S.W.)

This combination supplies a distinct want. The food is composed of essence of beef, with cream and yelk of egg. It is a whitish-yellow jelly contained in hermetically sealed tins. Its taste is pleasant and suggestive of custard. We found no objectionable preservatives. It is prepared for the use of European travellers and others in tropical climates where fever is prevalent and where cream and yelk of egg are often difficult to obtain.

STARLIGHT SOAP.

(LEVER BROTHERS, LIMITED, PORT SUNLIGHT, CHESHIRE.)

We have carefully examined this soap and find that it fulfils all the requirements of a detergent intended for the skin. It has a greenish tint and is agreeably and delicately scented. According to our examination the quality of the ingredients used is beyond reproach. Our experiments showed the soap to be absolutely free from alkali or other objectionable substances. The soap contains a minimum of moisture and while it lathers well it does not do so too freely or extravagantly.

OLD SCOTCH CREAM WHISKY.

(R. H. THOMSON AND CO., 130, CONSTITUTION-STREET, LEITH.)

This spirit is probably correctly described as a "pure malt whisky." It possesses a smooth mellow flavour and the delicate character of a matured and malt-derived alcohol. The results of analysis were as follows: alcohol, by weight 40·30 per cent., by volume 47·67 per cent., equal to proof spirit 83·54 per cent.; extractives, 0·79 per cent.; mineral matter, *nil;* acidity calculated as acetic acid, 0·025 per cent. These results are consistent with the statements concerning the character and purity of the spirit.

STERILISED CREAM AND MILK.

(THE DAHL MILK CO., DRAMMEN, NORWAY; AND H. FRANCIS AND CO., 8, ARTHUR-STREET WEST, E.C.)

Both these preparations were found to be satisfactorily sterilised. Their respective analyses were as follows. Cream: water, 68·55 per cent.; fat, 23·32 per cent.; mineral matter, 0·53 per cent.; curd, &c., 7·60 per cent. Milk: total solid matter, 11·77 per cent.; fat, 2·90 per cent.; and mineral matter, 0·64 per cent. According to these results we cannot regard the products as presenting a rich composition, although some allowance must be made for the difficulty of obtaining a satisfactory sample for analytical operations. The cream and milk, however, were both thoroughly whipped before a sample was decided upon. The flavour of the cream was excellent and the milk also was not marked by any pronounced boiled flavour.

ST. RAPHAEL QUINQUINA WINE.

(BOWEN AND MCKECHNIE, CROSS-STREET, FINSBURY.)

We have examined this wine on a previous occasion, but it has since been modified, chiefly in regard to the wine employed as a menstruum of the cinchona bitters which it contains. While agreeing that the wine is undoubtedly of tonic value we do not think that this change has altered its character for the better, especially in regard to taste.

FERRU COCOA.

(THE FERRU COCOA MANUFACTURING CO., 329, GOSWELL-ROAD, E.C., AND QUEEN-STREET, CARMARTHEN.)

Normally cocoa contains no iron and its addition in an organic form in the preparation before us is a step of some importance. According to our analysis the cocoa contains 0·3 per cent. of iron in the form of albuminate. We were able also to separate a small quantity of caffeine, the alkaloid of kola. In addition, the cocoa contains a small proportion of malt. The astringent matters of the cocoa do not appear to interfere with this form of iron, so that the iron probably reaches the alimentary canal in the same condition (of albuminate) in which it is added to the cocoa.

CAPTOL.

(4711 DEPOT, 62, NEW BOND-STREET, W.)

Captol is a pleasantly-smelling limpid alcoholic fluid containing chiefly chloral and tannin in a state of combination. It is described as a hair tonic, this property being referred to the tannin as a specific for reducing secretion and to chloral on account of its anti-parasitic action. The unpleasant effects of each in separate form are said to be avoided by this particular combination known as captol. Our analysis confirms the presence of the constituents stated as well as of small quantities of resorcin and salicylic acid. We have tried this preparation clinically and found it not only pleasant to use but apparently effectual in preventing the formation of dandruff. It is said to have given excellent results in reducing the secretions of the sebaceous glands and in preventing premature baldness.

HORSERADISH MUSTARD.

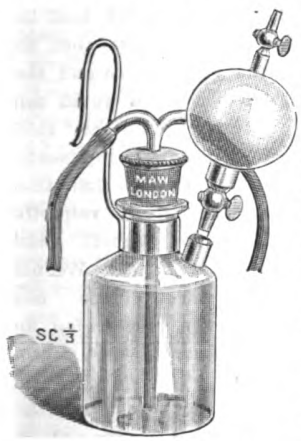
(C. H. SENN, 329, VAUXHALL BRIDGE-ROAD, S.W.)

This is an interesting addition to the list of table delicacies. In it is preserved the pleasant and peculiar aroma of fresh horseradish. It presents the appearance of ordinary mustard paste, but is lighter in colour. It affords an excellent condiment.

THE CHEMICAL PROFESSION.—The Presidents of the Institute of Chemistry of Great Britian and Ireland, the Society of Chemical Industry and the Society of Public Analysts entertained a large company at a reception held at the galleries of the Royal Institute of Painters in Water Colours, Piccadilly, on May 24th. The visitors were received by Dr. Stevenson, Dr. Clowes and Dr. Bernard Dyer and their wives. The gathering was a great success judging from the crowded state of the galleries. It was difficult to appreciate to the full the excellent programme provided, which included the admirable collection of water-colour paintings on the wall and a selection of music given by well-known artistes. There were several well-known members of the medical profession present.

New Inventions.

A NEW GONORRHŒA SYRINGE.



THE syringe which the accompanying figure illustrates I have termed the "opposite current" gonorrhœa syringe. I claim for it the following advantages: There are opposite currents—a single forward current and several backward currents. The backward currents, which are facilitated by grooves on the pipe, are essential for thorough cleansing of the urethra, while the forward currents will irrigate thoroughly any infective material which may have been pushed forward by the instrument during introduction of the pipe into the organ. The pipes are made of vulcanite and so will not be liable to be affected by the chemicals used in the injections. They are made of different lengths. The suction-tube feeds the ball continuously, so that there is no need of introducing the pipe into the organ more than once to effect a thorough cleansing.

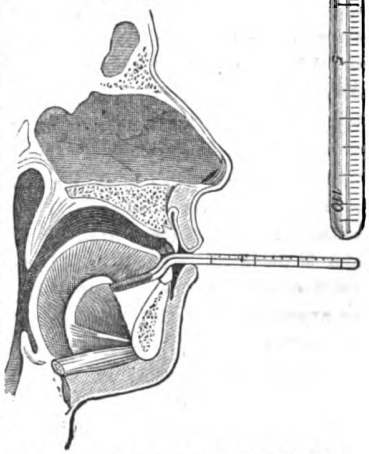
I believe this principle of opposite currents to be a novelty in syringes for the treatment of gonorrhœa. The makers are Messrs. Arnold and Sons.

S. MALLANNAH, M.B. Edin.
Ramkote, Hyderabad, Deccan.

AN A.C.E. AND CHLOROFORM APPARATUS.

THIS apparatus has been introduced in order that A.C.E. may be used in throat and nose cases through a nasal tube, thus obviating the use of chloroform alone. The additional safety of A.C.E. has been proved by experience, mortality from its use standing midway between that of chloroform and ether. The following is an extract from a lecture by Dr. Dudley Buxton: "I still feel bound in the light of our knowledge to say that chloroform should never be given unless there is some cogent reason for substituting it for ether or mixture." In operating upon the nose and mouth, where a tube must be used instead of a facepiece, it has formerly been absolutely necessary to use chloroform, the chloroform being administered by means of a Junker. If A.C.E. be administered by means of a Junker the ether evaporates more rapidly than the chloroform. The patient, therefore, receives a large dose of chloroform at the end of the operation at a time when he can least withstand it. In this apparatus a reservoir is formed by a bulb which communicates with the bottle. By means of a tap small quantities are added during the operation. The advantages claimed are that the percentage of chloroform remains the same throughout. A nasal tube method of anæsthesia becomes as safe, as convenient, and as reliable as when a facepiece is used, there being no need to use pure chloroform. Pure ether may be placed in the bulb and added to the A.C.E. mixture or chloroform should symptoms arise indicating any such proceeding. The anæsthetic never runs short. The apparatus can be immediately changed into an ordinary Junker. If chloroform is used in this apparatus a small quantity can always be retained in the reservoir or bottle without refilling. I have tried bulbs of various sizes and have found that one holding between one and a half and two ounces to be the most convenient. Another method of using the apparatus is to place pure ether in the bulb and A.C.E. in the bottle. The ether should then be added from time to time in small quantities, thus keeping the A.C.E. at the same strength. In over fifty cases in which I have used this apparatus only once have I had the slightest trouble. In this case a boy, aged twelve years, robust and with red hair, requiring an unusual amount of anæsthetic, came partially out of deep anæsthesia. I was using pure ether in the bulb so perhaps the amount of chloroform vapour he received was too small. The apparatus, I am confident from the number of times I have dropped it, is no more breakable than an ordinary Junker. The price of the apparatus (which can be obtained of Messrs. Maw, Son, and Thompson) is about the same as that of an ordinary Junker. The price of new bulbs can be counted in pence.

ALFRED J. HULL, M.R.C.S. Eng., L.R.C.P. Lond.
Hanover-street, W.



A NEW CLINICAL THERMOMETER.

IN taking a patient's temperature difficulty is sometimes experienced in making the patient place the thermometer in the right position in the mouth and also in its retention there. These difficulties are greatly reduced by using a thermometer which has been made for me by Messrs. Down Bros. It has a double bend in it, as shown in Fig. 1, for which the following advantages are claimed: 1. That it is more comfortable to the patient. 2. That it naturally falls into a better position in the mouth. 3. That it is more easily retained in position. 4. That the tongue can lie right down on the bulb and there is no space left in the floor of the mouth for saliva to collect. 5. That the temperature is taken in a shorter time and is more accurate as the bulb is thoroughly covered by the tongue and is in complete contact with the mucous membrane of the tongue and mouth. It does not lie in a pool of saliva or in such a position that the air can pass freely over it. In order to demonstrate these qualities it is only necessary to place first the wrong end of the thermometer in one's own mouth and then the bulb end, when at once the great difference will be appreciated.

FIG. 1.

FIG. 2.

A. HEYGATE VERNON, F.R.C.S. Eng.
Boscombe, Bournemouth.

THE LANCET.

LONDON: SATURDAY, MAY 28, 1898.

ON the opening day of the session the General Medical Council was reinforced by a Crown Representative—in the place of the late Sir RICHARD QUAIN—whose appointment has a significance which calls for notice. Public expectation in the profession had contemplated the election either of a general practitioner of good standing or of a registered medical man of high position practising dentistry. The general body of practitioners will not feel quite satisfied till one of the Crown nominees is appointed from its own ranks, and it can scarcely be other than an oversight that such an appointment has not yet been made. In the minds of statesmen the medical profession should not mean only the select few who fill the offices of the medical corporations or the chief chairs in medical schools. The medical profession must be taken to include the busy practitioners who do the real public work of the profession by night and day and upon whose efficiency the health and life of the people so much depend. One or two Crown appointments on the Council for this sort of member would to a certain extent meet the demand for a better representation of the profession as a whole in the General Medical Council. Meantime the appointment of Mr. CHARLES SISSMORE TOMES, F.R.S., F.R.C.S. Eng., and L.D.S., to be for five years a Member of the General Council of Medical Education is one that has much to commend it. The position which Mr. TOMES holds in the profession and in the Schools of Dentistry, his Fellowship of the Royal College of Surgeons of England, and his researches into the development and structure of the teeth in various animals make him at once an ideal representative of dentists on the Council and a valuable acquisition to a body which, in addition to supervising medical education, has to regulate the teaching of dentists and to a growing extent their practice. It is undeniable that the dentists have claim to some representation, and in discussing the appointment before it was made we allowed this to be the case, although we held, and still hold, that the voice of a general practitioner is just now more required in the deliberations of the Council. But it must not be forgotten that the dentists contribute towards the Council's funds, are subject in some degree to the Council's authority and regulations, and are liable to incur its censure and even erasure from the Dentists' Register. Until a Direct Representative of their order is provided by law it does seem reasonable that they should occasionally be recognised in a Crown nomination. The appointment of Mr. TOMES, who is at once a medical man and a dentist, is also opportune, as the Council is being called on to define its views and recommendations on the subject of dental education and examinations and as there is a collision of opinion between those who estimate dentistry as a merely mechanical trade and those who would require the whole science of medicine and surgery to be learnt by the practitioners of the useful specialty.

An acute encounter between Mr. VICTOR HORSLEY and the President, Sir WILLIAM TURNER, marked the opening of the session. As our readers know, Mr. HORSLEY, in one of the reports which he thinks it his duty to issue from time to time to the registered practitioners of England and Wales (and which we consider it our duty to publish to Mr. HORSLEY'S constituency), said that immediately on his appointment the President "committed a deliberate attack on the rights of individual members of the Council and a new and very serious infringement of constitutional government" in debarring a member of the Council from inspecting certain documents in the archives of the Council. Mr. HORSLEY is a man with the courage of his opinions and he put down on the programme a motion intimating that "at the earliest convenience" he would call attention to this action of the President. The President was equally anxious to have such a charge disposed of and it was discussed within an hour of the commencement of the business of the Council with the result that without proceeding to division the whole Council upheld their President's action. The question raised was one of great importance and, later, was settled in a sense satisfactory to Mr. HORSLEY and anyone wishing to make reasonable use of the documents of the Council. It is probable that Mr. HORSLEY had no intention to give a personal character to the discussion. Those who best know his keen interest in such questions will find it most easy to believe that he only meant to raise a constitutional point of great importance. On this view it is to be regretted that he did not wait for the meeting of the Council. The end he has in view would have been gained more easily and without exciting that attitude of opposition to himself which was still maintained in regard to his subsequent motion, seconded by Dr. GLOVER, for a committee to inquire into the conduct of the legal business of the Council. On this subject we cannot think that the Council was quite well advised. We believe that the lawyers of the Council have done good service and that the investigations of an impartial committee would only have emphasised the fact. It is absurd to think that lawyers are so thin-skinned as they were represented to be by some of the speakers, or to say that there was anything essentially unreasonable in a respectful inquiry into the legal business of the Council, which is necessarily difficult and complicated. On Wednesday a second and highly important debate took place, on the motion of Dr. GLOVER, concerning the regulations under which the documents of the Council shall be accessible to its members. The speeches and division showed that the Council was actuated by the double desire to secure the safety of its documents and at the same time to make them available for the use of members in any reasonable way and for any reasonable purpose, while it was felt to be necessary that special care should be taken to ensure that all information so gained relating to penal cases should be regarded as confidential. We venture to hope that the regulations, for details of which we

refer our readers to our report of the day's proceedings, will work well. They ought to facilitate all proper use of the documents which are confidently declared by the counsel of the Council to be its property and not that of any of its individual members. This seems to be sound doctrine but it must not be interpreted so as to render such property useless for the guidance of members who are heretical enough to think that the Council has not reached absolute perfection in the management of its business and the exercise of its powers.

We were sanguine enough last week to hope that the Council had disposed for some time of the question of the Midwives Bill, but such is not the case. By formulating its views with great care at the request of the Privy Council it has induced the Lord President to advise the promoters of legislation to come to an understanding with the General Medical Council as representing the profession. The promoters have asked for a conference with either the Council or a committee of the Council. The Council has appointed a committee with the understanding that they will listen to what the promoters of the Bill have to say but will not be in a position to alter the expressed views of the Council on the matter. They will, in fact, whatever words are employed, "receive a deputation," but they will not take part in a conference.

IT is matter for serious regret that neither the last nor the present Government has recognised the need for legislative action to remedy the defects of existing provisions for certifying causes of death upon which so much light was thrown by Sir WALTER FOSTER'S Committee a few years since.

The Registrar-General's fifty-ninth annual report, dealing with the vital statistics of England and Wales in 1896, contains a most valuable analysis of facts and figures relating to uncertified causes of death in recent years and to their local distribution which deserves the careful attention of all who are interested in this important but neglected subject. This report shows that during 1896 the number of deaths registered in England and Wales was 526,727; of these deaths the causes of 482,109, or 91·5 per cent., were certified by registered medical practitioners, and of 32,990, or 6·3 per cent., by coroners after inquest, while the causes of the remaining 11,623, or 2·2 per cent., were registered as uncertified, no certificate being available in these cases either from a registered medical practitioner or from a coroner. It is satisfactory to learn that the proportion of these uncertified deaths is steadily, if slowly, declining; it was 3·8 per cent. in 1881-85, 3·1 in 1886-90, 2·5 in 1891-95, and had further fallen to 2·2 in 1896. The percentage of these deaths in 1896 ranged in the various counties from 0·6 in London, 0·9 in Wilts, 1·0 in Somerset, and 1·1 in Monmouth, to 4·2 in Hunts and Warwick, 4·5 in North Wales, and 4·6 in Hereford. Before, however, discussing the distribution of these deaths in greater detail it will be well briefly to notice a useful table given in the report showing the 11,628 uncertified deaths classified according to age and assigned cause. The first noticeable fact is that 6704 of these uncertified deaths were of infants under one year of age and 2200 of persons aged upwards of 65 years, the remaining 2724 being of children and adults aged between one year and 65 years. Among infants aged under three months 6·2 per cent. of the causes of death were uncertified, while the proportion decreased rapidly at subsequent age-periods and was lowest, 0·7 per cent., between 15 and 25 years; among persons aged upwards of 65 years the proportion rose again to nearly 2 per cent.

As regards the assigned and registered causes of uncertified deaths it should be pointed out that the registrar is instructed before registering a death to ascertain whether any registered medical practitioner was in attendance during the last illness of the deceased person or whether an inquest has been held, and in either case to require the production of the statutory certificate of the cause of the death. In case no such certificate can be obtained, and in case the circumstances do not require him to report the death to the coroner, the registrar is instructed to obtain from the ordinary informant of the death the best available information as to the cause of death for insertion in the register as an uncertified cause of death. Uncertified deaths consist for the most part of cases in which there was no medical attendance during the last illness of the deceased or in which the attendance was of an unqualified or unregistered practitioner. As a matter of fact, it appears that some cause was assigned for all the 11,628 uncertified deaths in 1896 excepting only in 625 cases, in which the cause of death was returned as "unknown." It is not surprising to learn that in a very large proportion of these cases the assigned cause is distinctly indefinite—for instance, 2899 deaths were returned as due to convulsions, atrophy, or debility, 208 to teething, 213 to diarrhœa, 767 to old age, and 1791 to premature birth and congenital defects. Among the more definite causes assigned to uncertified deaths may be noted 236 from measles, 25 from diphtheria, 24 from small-pox, 111 from whooping-cough, and 31 from scarlet fever. Child-birth was the assigned cause in 45 cases, cancer in 53, and no fewer than 204 uncertified deaths were referred to different forms of violence.

These 204 uncertified deaths attributed to violence bring us naturally to the most important part of the Registrar-General's recent statistics bearing upon this subject. The assigned cause of death in uncertified cases has obviously little real or scientific value, but it may at any rate be assumed that at least these 204 deaths were actually the results of violence, and as a commentary upon the present state of the law it is useful to consider how it was possible for these deaths to be registered without due inquiry and certification and the holding of an inquest as distinctly directed by law. Registrars are strictly instructed to report to the coroner previously to its registration every death caused directly or indirectly by violence or attended by suspicious circumstances, as well as all deaths the causes of which are unknown and all sudden deaths the causes of which are uncertified. There is little reason to doubt that registrars with only occasional exception carry out these instructions, more especially as regards violent deaths, the breach of which necessarily involves reproof from the central office, and the Registrar-General now tells us for the first time

some of the results of the reference of deaths to the coroners. It appears that within the knowledge of the Registrar-General 42,644 deaths were reported to coroners in 1896; that in 32,990, or 77 per cent., of those cases inquests were held, while in the remaining 9654, or 23 per cent. of the whole, the coroners decided that inquests were not necessary. It appears from the table given in the report under notice that of 100 deaths referred to coroners in the several counties in 1896 the proportion of inquests held did not exceed 40 in Warwick, 55 in Essex, 56 in Hereford, and 57 in Huntingdon and in Dorset; whereas the proportion ranged upwards to 89 in Northumberland, 90 in Monmouth, 91 in Wilts, and 94 in London. As registrars perform their duties under precisely identical instructions and superintendence throughout England and Wales, it must be assumed that these wide variations in the relation of inquests to reported deaths is due to the varying discretion of coroners as to the necessity for holding inquests. The Registrar-General reports that the large majority of the 9654 deaths reported to coroners but concerning which no inquests were held were registered as uncertified, but that in about 1400 of the cases medical certificates were duly obtained. He concludes, therefore, from a careful analysis of the documents in his possession, that of the 11,628 uncertified deaths in 1896 about 8228, or 71 per cent., had been reported to coroners and thus subjected to some kind of investigation, although no inquests were held and the causes of death were necessarily registered as uncertified. It follows, therefore, that not more than about 3400 of the uncertified deaths had not been reported to coroners.

These statistics conclusively prove what has frequently been asserted in these columns (based on the constant relation between the proportion of inquests held and of uncertified deaths), that under the present conditions of registration law a certain number and proportion of uncertified deaths are governed by the varying action of different coroners in the exercise of their discretion as to the necessity for holding inquests. In London and Wiltshire, for instance, in which the coroners held inquests in 94 and 91 per cent. respectively of the cases reported to them, the percentage of uncertified deaths in 1896 was only 0·6 and 0·9 respectively; whereas in Essex and Warwickshire, where the coroners held inquests in only 55 and 40 per cent. of the reported cases, the percentage of uncertified deaths was equal to 3·6 and 4·2 respectively. No stronger proof of the neglect of some coroners to perform their statutory duties in certain cases is needed than the reported fact that 204 deaths from violence in 1896, presumably reported to coroners, were registered as uncertified because no inquests were held.

The Registrar-General's statistics are to some extent satisfactory, proving as they do that more than 70 per cent. of the deaths reported by him as uncertified in 1896 were subjected to some kind of investigation by coroners and were considered by them to be cases in which inquests were unnecessary. From another point of view it is satisfactory to know that, pending further legislation on the subject, the proportion of uncertified deaths may be reduced to a minimum by the action of coroners, as it is beyond question that the high proportion of uncertified deaths in Warwickshire, for instance, is the direct result of the low proportion of inquests held in that county, while the low proportion of uncertified deaths in London is as surely the result of the high proportion of inquests held within that county. It is evident, however, that some provision is urgently needed in order that it may be impossible for any death to be registered or any order for the burial of the body to be issued unless the cause of such death has been duly certified either by a registered medical practitioner or as contained in the verdict of the coroner's jury after the holding of an inquest where medical evidence has been given. With regard to the cases of uncertified deaths referred to in the Registrar-General's report further provision should be made by which *all* such cases before registration should be referred by the local registrars to the coroner for investigation. The coroner should be empowered in the course of his inquiry, when no inquest is necessary, to engage the services of a medical practitioner, upon whose certificate of the cause of death, after investigation with or without post-mortem examination, the death should be registered as "certified." By such regulations, which a few clauses in an Act of Parliament could establish, no uncertified death would be registered, and the accomplishment of this most necessary reform could be effected at a comparatively small additional expenditure from the borough or county funds out of which coroners and the expenses connected with inquests are now paid.

WE have frequently thought that people in this country have never thoroughly realised the great obstacles which had to be overcome and the hardships which had to be encountered by the troops taking part in the late Tirah expedition. The nature of the country with its great topographical difficulties—naturally lending themselves to its strong and easy defence by the numerous warlike tribes of trained marksmen inhabiting it — presented altogether different conditions from those which obtain in the Soudan for example. The Afridis took care not to concentrate in any numbers so as to afford an opportunity for any general engagement like that of the brilliant affair with the Dervishes at Atbara. Whatever may have been said and thought of the design of the Tirah expedition it was nevertheless thoroughly carried out and, as subsequent events have shown, it has proved successful, for it has attained its object—namely, the penetration of the Tirah territory, the defeat of the tribes, their pacification and submission. Allegations have been made—whether justly or unjustly we cannot say—regarding the inefficiency of some of the officers composing the military staff of the army in the field; but we are proud to say that the efficiency and good work performed by the medical services have throughout the campaign been generally recognised. We shall have to refer, too, to an application of one of the latest advances of science during the Tirah campaign which proved of great practical value in military surgery and speaks well for the up-to-date enterprise and care of the medical service. Although we have already published a paragraph on the "Health of the Tirah Field Force" in THE LANCET of May 21st under the heading of "The Services," yet some of its statements well merit brief recapitulation. The maximum number of British

troops employed at any one time in the late military operations on the North-west Frontier of India, extending from June, 1897, to February, 1898, was 18,000. Taking one item only—that dealing with the extent of invaliding—it appears that up to April 12th, 1898, only 489 men passed through Deolali as invalids to England, including 106 suffering from gunshot wounds, 163 from ague, and 202 from all other diseases. This low percentage speaks volumes for the endurance of the troops and the efficiency of the hygienic, medical, and commissariat arrangements provided for the army in the field, especially when it is contrasted with the terrible results of our experience in the Crimea forty years ago. The progress which has since then been made in these respects, as in every other connected with modern warfare, is simply immense.

Of the results, moreover, of modern science as applied to military surgery we have a striking illustration in the late application of the Roentgen rays in warfare as set forth by Surgeon-Major W. C. BEEVOR of the Army Medical Staff in his extremely interesting lecture at the Royal United Service Institution on May 20th last. Surgeon-Major BEEVOR had charge of the apparatus supplied for the use of the Indian Frontier Expedition, where for the first time it formed part of the equipment of the regular medical service in the field. He gave a very instructive history of what had been accomplished through the instrumentality of the x rays, illustrated by examples drawn from experience, which showed indubitably that even in savage warfare and under the most unlikely and adverse conditions the apparatus could be, and was, successfully applied in the prevention and relief of human suffering. Nor was his lecture wanting in a truly practical aim, for he proved that this new method of applied science could be carried anywhere and used with the troops operating in the field in front as well as at a base hospital in their rear. He came to the conclusion, however, that human transport is for this purpose by far the safest and most satisfactory in every respect. His dhoolie bearers succeeded in carrying the necessary apparatus—the battery, delicate glass tubes with their platinum terminals, conducting wires, &c.—slung on a pole, from Bagh camp in Tirah, down the defile to Dwatoi and down the Bara Valley to Peshawur without injury. There is no need to remind readers of THE LANCET of the extreme usefulness of the Roentgen rays in military surgery, for this has already been so established as to be sufficiently obvious. It only now remains to discover whether any, and if so what, modifications can be introduced for better adapting the apparatus to the varied conditions of war over and above those which had suggested themselves in the late frontier expedition. We consider that the highly satisfactory results obtained by Surgeon-Major BEEVOR and his *confrères* are interesting and extremely creditable to the scientific energy and enterprise of the military medical service.

BRISTOL ASYLUM.—The report of the committee for 1897 shows that at the end of that year the number of patients was 751 (373 males and 378 females); of these 673 were chargeable to Bristol. Considerable progress is being made with the enlargement of the asylum, by which means increased accommodation will be provided for 139 additional patients.

Annotations.

"Ne quid nimis."

FIRST REPORT OF THE PRINCE OF WALES'S HOSPITAL FUND.

THE first report of the committee of this Fund is before us, and although, as is well known, the income secured is far short of that which is desired, the Fund reached a very large sum. The total amount collected up to Dec. 1st, 1897, was £227,551 12*s.* 7*d.* Of this amount the sum of known annual subscriptions reaches £21,443 1*s.* 5*d.* The total amount distributed among the various hospitals in 1897 was in round numbers £57,000, and there has been invested the sum of £167,020 19*s.* 8*d.* The income arising from this and the known annual subscriptions will provide altogether an annual income of about £25,000, which, however, is but a quarter of the sum desired every year. The amount distributed as annual grants was £22,050 and the special donations in honour of Her Majesty's Diamond Jubilee amounted to £34,776 5*s.* There is one point about the Fund which reflects the highest credit on the committee and the officials and that is that the whole sum of £227,551 12*s.* 7*d.* was collected at an expenditure of only £3704 7*s.* 9*d.*, being a percentage of £1 12*s.* 6*d.* The promised annual subscriptions range from £1000 to 1*s* and the donations from £12,500 to 6*d.* We are glad to see that the distribution committee say:—"To open wards closed for want of funds is certainly a most important object; and on the understanding that we are dealing with the income of the Fund, and that a sum given to any hospital this year for the purpose under consideration will probably be continued in future years and so may be regarded as a grant of so much *per annum*, we have recommended that considerable sums be so employed. ..... It would be mere mockery to invite any institution to undertake the opening of closed wards by making a grant to it this year unless there were some reasonable prospect that a similar provision could be made in the future." The needs of the London hospitals are only too well known and we can only hope that the fervour of the Diamond Jubilee having in part died away the charitable—and by this we do not only mean the rich but those who could easily afford some small sum—will not be prevented from renewing or in only too many cases fro commencing their subscriptions.

THE VALUE OF A DIPLOMA IN PUBLIC HEALTH.

NOT a few of those many medical men who within recent years have obtained diplomas in public health from one or another of the qualifying bodies will fail, we much fear, to reap a due pecuniary reward for all their labours. We use the term pecuniary reward advisedly since nothing can take from the possessors of these diplomas the enhanced interest in matters sanitary and social which the knowledge they have thus acquired confers upon them. The disappointment to which reference is made will arise in the main from paucity of appointments and from poverty of pay; but in spite of this it will come as a surprise to many to hear that in some appointments the possessors of experience and of diplomas will be sent away while the owners of neither will be elected. Such, however, has recently been the case in Essex, when, on the creation of a new urban sanitary district out of part of a rural sanitary district, the necessity to appoint a medical officer of health arose. Here there were, we are informed, three applicants: one, the holder of an M.D. degree, who was the medical officer of health of the rural district out of which the new district has

been created, and whose name is well known amongst East Anglian sanitarians; another, besides being a graduate in medicine and surgery, held two diplomas in public health. The third, the selected candidate, was, it appears, untutored either in the school of experience or of special diplomas, and held but the Licentiate of the Society of Apothecaries. What can we say as to this newly created urban sanitary body but that it, too, presumably possesses neither experience nor diploma? We are afraid that this view of the situation does not excuse the action of its members, because the want of experience from which they suffer should surely have induced them to obtain an experienced officer to guide their faltering footsteps. Fortunately the Local Government Act of 1888 has done much to prevent abuses of the kind to which reference is here made and renders it very improbable that a district with a population of some 50,000 will be saddled with a medical officer of health who has had no special training for the post.

"THE MEDICINE MAN."

MEDICAL men have frequently been presented on the stage and almost invariably as beneficent agents, but the stage "doctor" who is a villain is something more or less new. Dr. Tregenna, the practitioner in question, is a very clever man and much run after by fashionable people, none the less because he is an unorthodox practitioner, although he does possess a real power over his patients. He has studied the secrets of the brain and exercises his influence by will power mainly, though at times he employs "suggestions" as well. It will easily be imagined what sort of representation Sir Henry Irving gives of such a character. Tregenna is decidedly an uncanny person and selects his patients or victims from all classes of society. In the opening scene we see him in an East-end mission room, where he exercises his influence over costermongers and dock labourers and informs a gentleman of the former calling that he can listen to his brains as well as his heart. Here we might mention, as Sir Henry Irving is always careful about minutiæ, that the small end of a single stethoscope and not the large is the right one to apply to the patient. The finale of the first Act is decidedly impressive. One of Tregenna's patients is a drunken bully named Bill Burge, magnificently played by Mr. Mackintosh. Tregenna is determined to get this animal, "my tiger," as he calls him, into his Retreat, but Burge objects and in forcible language goes out into the night. "He will come when I want him," says Tregenna and sits down alone, except for the presence of a foolish parson, before the fire. There is silence in the room, only outside is heard the noise of oaths, screams, and an organ. Tregenna remains motionless and thinking; presently the door opens and Burge wanders in like a man in a dream. "My tiger has come back from his jungle, you see," says Tregenna, and the curtain falls. The last three Acts take place at "The Retreat" where, Sylvia Wynford, the daughter of a woman whom Tregenna had loved and whom in revenge on the man who had married her he is resolved to render insane, is a patient, for, as he says, "the will that can cure a disease can also bring it on." So he sets himself to bring about this disease—namely, melancholia—from which Sylvia's mother had suffered, and succeeds. Miss Terry is excellent here, as might have been expected from her playing of Ophelia. Bill Burge is also a patient in "The Retreat" and under Tregenna's influence has become as meek as a new-born lamb, a change which does not commend itself to his wife, who comes to see him. Mrs. Burge, admirably played by Miss Dolores Drummond, is furious with Tregenna for taking all her husband's spirit out of him, and this is the most realistic scene in the play. The end of the drama is that Tregenna, on learning that Sylvia's father had never heard of him when he married his wife, restores Sylvia's reason to her. Burge suddenly develops homicidal mania and goes for Tregenna with a knife. But the old will power still asserts itself and "the tiger" drops his knife. Then, however, Tregenna makes his fatal mistake. "Back to your den," he says, trying to push Burge out. But Burge immediately feels his immeasurable superiority in physical strength, throws Tregenna on the sofa and slowly strangles him. This scene, with the one exception that Sir Henry Irving omitted the asphyxial convulsions, was startling in its realism. We cannot praise the drama as a play, but Tregenna has a masterly exponent and should Sir Henry Irving correct the two little errors we have pointed out from a medical point of view he would make his rendering of an improbable character practically perfect.

SIGNS OF ABATEMENT OF THE SMOKE NUISANCE.

RECENTLY we have written strongly on the shameful way in which the air of the metropolis has been befouled by the almost solid outpourings of the chimneys of hotels, restaurants, and other buildings. We note with satisfaction that there are signs of our action having had good effect. Already we have observed an improvement in the neighbourhood of THE LANCET offices. This is due doubtless to the action of the London County Council, and at their last meeting (on May 24th) it was stated that a letter had been sent to no less than twenty-three vestries and district boards in London in whose districts the most serious nuisance from smoke has recently been observed. We trust that the Council will continue their vigilance in this matter as there is no possible excuse for the existence of such an undoubted evil.

ANNUAL MEETING OF THE WORKHOUSE INFIRMARY NURSING ASSOCIATION.

THE annual meeting of the Workhouse Infirmary Nursing Association was held on May 19th at the house of the Hon. Mrs. Reginald Talbot, Dr. T. D. Savill being in the chair. The past year has been a somewhat eventful one for the association, which has lost its President by the death of H.R.H. the Duchess of Teck and the honorary secretary by the resignation of Miss Wilson through ill-health. The latter, however, retains her connexion in the capacity of treasurer. As already recorded in these columns the association contemplates bringing its labours to an end, in the belief that the magnitude of the task is no longer within the scope of private enterprise. The difficulty of finding suitable candidates and of raising the necessary funds for their training appear to be the chief reasons which have influenced the committee in this decision. But, as we have already pointed out, surely these are not new obstacles in the work of the association, and it is only necessary to compare the state of nursing in workhouses now with the condition of matters when the movement was started, at the initiation of Miss Twining and the Marchioness of Lothian in 1879, to show how successfully it has coped with them. Moreover, the recent "Nursing in Workhouses Order" issued by the Local Government Board, which is largely due to the efforts of this body, though it may not do all that is wanted, is a large step in the right direction and should certainly tend in time to make the service more popular in the nursing world. We are glad to notice that the chairman in his opening remarks stated that the association does not intend to bring its labours to a close but only to forego the training of probationers. It will continue to look after the interests of the nurses still attached to the

association and to advise boards of guardians in difficulty and help them as far as possible. The difficulty experienced by county and provincial guardians in procuring nurses is really becoming acute and unless something can be done the "Order" referred to will be in danger of becoming a dead letter from lack of trained nurses to fill the vacancies. We constantly hear of guardians advertising for months unsuccessfully, although offering, in some instances, fair and even handsome salaries. Is it not time that the question was submitted to the investigation of a departmental committee, so that the extent of the difficulty and the best means of remedy might be fully revealed?

THE BIRTHDAY HONOURS.

THE list of birthday honours is a small one and the representation of our profession in that list is small also. Surgeon-Lieutenant-Colonel J. G. Rogers, D.S.O., head of the Egyptian Sanitary Department, has been made a K.C.M.G., and Dr. Andrew Milroy Fleming, Principal Medical Officer of the British South African Police, has been made a C.M.G. Surgeon-Major-General Robert Harvey, D.S.O., has been made a C.B., and Brigade-Surgeon-Lieutenant-Colonel A. M. Branfoot, Professor of Midwifery in the Madras Medical College, has been made a C.I.E. It is noticeable that the navy has been neglected in the last distribution of birthday honours.

THE EDUCATIONAL THEORY OF THE UNIVERSITY OF WALES.

DR. ISAMBARD OWEN has recently delivered an address on the University of Wales and its educational theory to the members of the Teacher's Guild of Great Britain and Ireland, which address deals with the constitution and policy of the new University. It will, undoubtedly, do a great work in the future consolidation and organisation of university teaching in Wales, for although only founded in November, 1895, it has already 530 matriculated students in the three University Colleges of Aberystwith, Bangor, and Cardiff. After a full consideration the promoters of the University decided that non-collegiate students could not be successfully combined in one university with collegiate students, so that the members of the University will have to pursue at one of the Welsh colleges a prescribed form of curriculum. This curriculum is not drawn up so exclusively as to curtail the bias of teaching of any individual teacher, but the teacher's scheme in any of the colleges has to be finally agreed to by the University Court, after it has been submitted to the teachers in other colleges. It is therefore expected that a practically uniform standard for examinational purposes will be secured, whilst giving more freedom to individual teachers, than is the case where a rigid syllabus is laid down by the Senate of the University to which every professor and teacher must adapt his teaching, as is the case in the existing University of London. In so far as teaching is made to take precedence of the examination the charter scheme is undoubtedly drawn on proper lines. The advancement of knowledge by the encouragement of research, as well as the conferring of degrees, is also insisted on, and this is primarily the proper duty of any real university; but the mere presentation of a thesis or dissertation embodying independent work by a candidate for a degree requires a stricter interpretation than is usually the case. The University Court—the executive and legislative body—is comprehensive enough for even these democratic days, being composed of no less than 101 members — viz., 36 members from the University Colleges, 26 appointed by county councils, 13 by the Crown and a similar number by the graduates, 6 by the Central Board of Intermediate Education, 3 by the head masters and mistresses of public intermediate schools, and 3 by the head teachers of public elementary schools in Wales. The Chancellor completes the list and he is elected by the Crown and appointed for life. The University is to be congratulated on having the Prince of Wales as its first Chancellor. The constitution of the governing body is certainly unique, for it differs *in toto* from any other supreme university authority and may suit Wales, but is hardly likely to be followed by the founders of any future university. The advisory power is the University Senate, which is composed of the heads of the various departments of teaching in the several colleges, and with them the course of the University will rest, for obviously it can only be under most exceptional circumstances that the higher authority will neglect or set aside their recommendations. In passing candidates an external examiner has the final authority, although the Vice-Chancellor and internal examiners appointed by the three Colleges are joined with him in the Examining Board. The scheme is therefore in its essence a federation of colleges under the name of a university and does not materially differ from that of the Victoria University.

PLAGUE IN CHINA.

THERE is unfortunately only too much reason to suppose that plague is becoming increasingly prevalent in some of the coast cities of China. The following extract from the official returns for the present year published in the Hong-Kong newspapers shows that there is ample cause for anxiety with respect to that city:—

Week ended	Cases.	Deaths.
Jan. 1st	Nil	Nil
,, 8th	2	1
,, 15th	Nil	Nil
,, 22nd	2	2
,, 29th	2	4
Feb. 5th	5	3
,, 12th	5	5
,, 19th	9	6
,, 26th	46	42
March 5th	22	17
,, 12th	16	12
,, 19th	31	28
,, 26th	47	40
Total	187	160

"During the twenty-four hours up to noon, March 31st, 11 new cases and 10 deaths were reported, making the total since Jan. 1st (ninety days) 224 cases and 195 deaths." Plague is also said to prevail in Canton to the extent of about 100 cases a week, and to be increasing in Macao although the Portuguese authorities of the latter city are very reticent on the subject.

STREET NOISES.

THE judgment in the Kent County Council by-law case, upon which we commented in THE LANCET of May 21st, has, we are glad to see, attracted a great deal of attention both in the daily and the weekly press. We have received the prospectus of a new society—namely, the Society for the Suppression of Street Nuisances. Its ideals are admirable, only we think their scope is too wide. Certainly rowdyism, obscene language, solicitation, and unnecessary cries and noise ought all to be put down with an unsparing hand, but to take them all in hand at once would require another Hercules. The first two nuisances will never be put down until magistrates have the power and be obliged to exercise it of ordering a flogging for the members of the various gangs who go about with revolvers and knives. As for solicitation, that is an evil which it is almost impossible to stop. But noises can and

must be put down, and if the press, the society under consideration, and the sister Society for the Suppression of Street Noises, will only work hard, the County Council or somebody will be obliged to do something. For the present, however, we would advise the new society to confine its energies to the suppression of the last-named nuisance and after some peace has been restored to the streets then to turn its attention to the others mentioned in the circular.

SIR HERBERT KITCHENER'S DESPATCH.

SIR HERBERT KITCHENER'S despatch regarding the battle of Atbara has now been published, together with a special order to the Army, promulgated with the approval of the Secretary of State for War. The Commander-in-Chief, in conveying Her Majesty's congratulations upon the brilliant success of the recent campaign in the Soudan, dwells upon the able plan of the operations and the gallantry with which these operations were carried out and specially alludes to the great march of the British Brigade to the Atbara. Lord Wolseley concludes his Order by saying that "the good services of all those brought to notice will be considered at the conclusion of this year's operations." This carries our thoughts to the larger and more important campaign which remains to be undertaken for the capture of Khartoum and to the decisive battle which has still to be fought with the Khalifa's forces in order to decide the mastery of the Anglo-Egyptian power over the Nile valley. We heartily congratulate the medical officers of the British and Egyptian armies on the way in which their services, which were both difficult and onerous, are recognised. Sir Herbert Kitchener says: "The medical arrangements of the British Brigade under Brigade-Surgeon-Lieutenant-Colonel Macnamara and his staff, and of the Egyptian army under the direction of Brigade-Surgeon-Lieutenant-Colonel Gallwey and his staff, were, under the somewhat difficult circumstances of the operations, satisfactory, and the energy and skill displayed by the medical staff under their direction are deserving of much credit."

ANIMAL ODOURS.

THE lamentable accident which occurred the other day, resulting in the death of a little child from injuries received while driving in a brougham with his nurse, raises several other questions than the obvious and pressing one of the control of street nuisances. The horse in the brougham was frightened by the smell of a performing bear which was being led along in the street, ran away, the brougham collided with a waggon and was upset, and the child was killed. Horses are well known to be disposed to fits of unreasoning fright and no horse unless carefully trained can bear the smell of two animals—namely, the bear and the camel. The smell of the latter is offensive enough to human nostrils, but this would not explain the terror which a horse exhibits at first sight or smell of a camel. But the reason for the horse's dread at the smell of a bear must, we suppose, be found in a reminiscence continued through the race from the time when the cave bear fed upon the primitive horse. In the case of the camel it cannot be simply that the smell is disagreeable to the horse, for horses have no objection to goats, the smell of which, though not so offensive as that of a camel, is very similar in character. And on the other hand it cannot be, as in the case of the bear, the fear that the camel will do some harm. Animal odours, both human and otherwise, form a curious chapter in medical lore. In the *Journal of Cutaneous and Venereal Diseases* for July, 1885, appeared an abstract of a prize essay by Dr. Monin "Sur les Odeurs du Corps Humain," which contained a vast amount of information on the subject. It is well known that individuals of the same race possess various smells. For instance, the smell of red-haired people is often very offensive, a fact noted long ago by Ambrose Paré. The strong smell of the negro, too, has often been commented upon by travellers. Alexander the Great was said by Plutarch to emit a smell of violets, and several gynæcologists have noticed the peculiar aromatic odour, in no way offensive, given off by certain women during the menstrual period.

THE TEMPLES OF ÆSCULAPIUS.

As will be seen in our diary of coming events for next week Dr. Richard Caton will deliver on June 4th at the Royal Institution the first of a course of lectures on the "Temples and Ritual of Asklepios at Epidaurus and Athens." Much new and valuable information—of particular interest to medical men it should be noted—has been obtained lately concerning the Temples of Æsculapius. This information has not been as yet communicated to English audiences, but they could not obtain it from a better source than Dr. Caton, who has studied both the Hieron of Epidaurus and the Asklepion at Athens and who brings medical as well as classical knowledge to bear on the matter. The lectures will commence at 3 P.M. at the Institution, Albemarle-street, Piccadilly.

THE RELATION OF HOSPITALS TO INFIRMARIES.

THE Executive Committee of the Walsall and District Hospital recently received a deputation from the board of guardians of the neighbourhood with regard to a complaint that a patient had been discharged from the hospital and sent to the workhouse under circumstances which did not justify that course. Remarks had been made at a meeting of the guardians by members who evidently did not understand the principles which underlie hospital relief, but it is only fair to these gentlemen to say that when matters were duly explained to them they expressed themselves as satisfied with that explanation. It appears that a cripple was run over and brought to the hospital. He was bruised but not seriously injured and when well enough to be discharged was sent to the infirmary as he was a pauper. The allegation made against the hospital officials was that the patient had been sent to the infirmary before he was in a fit state to be discharged because he was a pauper, thereby suggesting that paupers were not so well cared for at the hospital as other patients. A full explanation was given by the secretary and others connected with the hospital, showing that any patient in a similar condition would have been sent home if he had had one to go to. The relation of hospitals to infirmaries is fairly well determined. Hospitals are intended for the relief of those patients unable to pay for medical or surgical attendance and nursing whose cases are considered severe enough for admittance as in-patients (we are not dealing here with the question of out-patients or outdoor relief), but there must be a reasonable hope that permanent or considerable temporary relief can be given. If the case is considered hopeless as regards further improvement or is likely to be considerably prolonged the patient is advised to go to the infirmary, where the subjects of such chronic cases receive competent medical attendance for the rest of their lives unless they sufficiently recover to earn their own living. As hospitals are intended for acute cases only and a certain number of beds have to be kept vacant for the reception of urgent cases night and day, it would be obviously unfair to such patients to have beds occupied by infirm patients who may live several years. There is frequently some unwillingness on the part of hospital patients to go to a workhouse infirmary; this can be readily understood, but the objections must be overruled for the sake of those whose lives timely medical or surgical aid may be effective in saving. Workhouse

infirmaries are now very different to what they were, although the nursing in many of them leaves a great deal to be desired; in others, however, it is everything which can be wished for.

CONSTANT PRESENCE OF THE PNEUMOCOCCUS ON THE SURFACE OF THE TONSIL.

THE pneumococcus may be found in the mouth as a simple saprophyte in healthy subjects. M. Wetter has shown that the inoculation in mice of the saliva of individuals who had not been subjects of pneumonia caused pneumococcic septicæmia in 20 per cent. of the experiments. He found the saliva of those who had suffered from pneumonia more virulent; in four-fifths of the experiments septicæmia was produced. At the meeting of the Société des Hôpitaux of April 15th, MM. Bezançon and Griffon showed by culture methods that the pneumococcus was present not frequently but constantly in the mouth. They had found that the serum of young rabbits aged about two months was a favourable medium for the cultivation of pneumococci. Mucus removed from the surface of the tonsil of forty individuals of all ages, some healthy and others suffering from various complaints, invariably yielded on this medium cultures of pneumococci. An important practical conclusion follows from this discovery. It is not sufficient to successfully inoculate the saliva or to make cultures from it to prove the presence of a pneumococcic affection. The expectoration or exudation must be directly examined and the presence of a large number of encapsulated diplococci which colour by Gram's method be proved.

RUMINATION IN MAN.

THE Journal of the American Medical Association, April 9th, 1898, contains an interesting paper by Dr. W. Sinkler on Merycism or Rumination in Man. This disorder was described as long ago as 1687 by the great anatomist Fabricius of Aquapendente and subsequently by numerous writers, but only a small number of cases has been placed on record. Rumination must not be regarded as simply vomiting of food. It is a return of food shortly after it has been swallowed unattended by nausea, retching, or disgust. The regurgitated food is either rejected or re-masticated and swallowed again. The act is analogous to the process of chewing the cud in the lower animals. To explain the latter a hypothesis has been put forward which, to say the least, is ingenious. The habit of rumination is thought to have been acquired by the herbivora when the carnivora first appeared on the earth. Fearful of attack the ruminants grazed rapidly ready for flight at the first intimation of danger; then having reached a place of safety their food was regurgitated and its mastication completed. In man various causes for rumination have been assigned, but the majority of writers agree that it is a neurotic condition; indeed, it must be regarded as nearly allied to neurotic vomiting. Heredity is a factor and may act indirectly through a neurotic diathesis. In one instance a grandfather, a father, and a son were affected. Rumination may be the result of imitation, as in the case of two children who copied the practice from a governess. The prognosis, as might be expected, is not good. Many cases improve under treatment, and often with no treatment there are intermissions of from one to three years, but sooner or later there is a relapse. In many cases patients voluntarily return to the habit either because they like to retaste their food or because the regurgitation relieves gastric distress. The treatment mainly consists in attention to the general health; in many cases the habit will be arrested as long as this is well maintained and return when it fails. If there is indigestion it must be corrected; here lavage may be useful. The diet should be carefully regulated and the amount of liquid reduced to a minimum. Thorough and complete mastication is essential. The patient should be trained to control the inclination to regurgitation.

THE INTER-HOSPITAL BOAT RACES.

THE usual races between representatives of the various hospitals were rowed on May 18th. The course was from Putney to Hammersmith Bridge. For the Senior Cup three hospitals sent boats—London, Middlesex, and St. George's. St. George's won the toss and they selected the middle station, apparently on account of the tide. Middlesex had the Middlesex and London the Surrey side. Shortly after the start Middlesex, being sheltered by the bank from a strong wind, drew ahead and opposite the boathouses were a length to the good, but they were evidently in want of training, and St. George's, whose crew contained two old "blues," rapidly overhauled them. Halfway up the course the St. George's boat was more than two lengths ahead of the London, whilst Middlesex were struggling gamely in the rear. An exciting race ensued between the first two boats. The London men rowed well against their formidable rivals. They were in splendid condition, which tells more than anything else in these races, and rapidly drawing level with St. George's, finally won by a clear length. In the race for the Junior Cup (presented for the first time this year) the Middlesex representatives easily beat those of the London Hospital. It seems a pity that more hospitals do not take an interest in and send crews for these events. Surely amongst such large hospitals as St. Bartholomew's, Guy's, and St. Thomas's there ought to be sufficient energy to induce four men to train and to endeavour to earn laurels for their schools. St. Thomas's, we understand, did enter but afterwards "scratched."

POST-GRADUATE CLINICAL STUDY IN THE METROPOLIS.

A SCHEME has recently been set on foot to provide clinical instruction for recently-qualified men after a coöperative fashion in the metropolitan hospitals and thus to offer to those concerned the advantages of clinical teaching hitherto sought in Paris, Vienna, or Berlin, by as far as possible collecting the scattered clinical material of the London hospitals together—i.e., by opening the teaching given in a number of hospitals to anyone who cares to comply with certain regulations. A reference to our advertisement columns will show that nine of the great London hospitals are coöperating in this matter. A ticket of admission valid for a three months' course costs 7 guineas, one for six months 10 guineas. These cards will admit their holders to any part of the clinical instruction at the several hospitals which is open to their own students, inclusive of operations and post-mortem examinations. They will be issued upon personal application any weekday except Saturday at the office of the Metropolitan Schools of Medicine, West Wing, Examination Hall, Victoria Embankment. Evidence of qualification must be furnished before a card can be issued. The system has only been in operation some three weeks and has already met with success, as, in our opinion, it thoroughly deserves to do. The wealth of clinical material in the London hospitals is enormous, but is so split up that it is not of such value as, for instance, that in Vienna, where it is practically all collected together in one building. Though of course this new system cannot alter the *locale* of the various hospitals, yet by enabling a learner to go from one to the other and to enjoy equal facilities at each it will go far to remove the disabilities under which clinical teaching in London has hitherto laboured as compared with foreign schools. All particulars may be obtained on application to the Honorary Secretary, Metropolitan Schools

of Medicine, at the Examination Hall, Victoria Embankment, W.C. The above scheme is a very laudable effort to improve matters with existing material, but it may be said against it that a qualified medical man cannot obtain the teaching he requires at the same time as an unqualified one. To obviate this an idea has been mooted of starting a post-graduate hospital and college at which instruction shall be confined to qualified men alone. The subject is such a wide one that we are compelled to reserve its consideration in full to a future issue.

HEPATIC ABSCESS CAUSED BY ASCARIS LUMBRICOIDES.

IN the *Deutsche Medicinische Wochenschrift* of May 19th Dr. Bruno Leick, assistant physician in the Greifswald University Clinic, describes a case in which a hepatic abscess was found to contain an ascaris lumbricoides. The patient was a shepherd's wife, thirty-five years of age, who began to suffer from pain in the region of the liver in February, 1897. In the end of May she observed a tumour above the navel and in June she was admitted to the hospital. She was then greatly emaciated and was obviously very ill; her temperature in the forenoon was approximately normal; in the afternoon it was raised, varying from 100·4°F. to 101·4°. Her abdomen contained a tumour larger than a child's head, which extended from the navel to the ensiform process, and by its elasticity, taken in connexion with the patient's enfeebled and hectic condition, suggested a suppurating hydatid. Laparotomy on July 7th disclosed a small encapsuled abscess lying in front of the liver, and a puncture which was made in its base passed through ¾ in. of liver substance into an abscess cavity containing yellow creamy fœtid pus. On July 10th, whilst the dressings were being changed, an actively moving ascaris was found in the abscess. The patient made a good recovery.

THE VACCINATION BILL: IMPORTANT COMMUNICATION FROM MR. T. W. RUSSELL.

THE following letter to Mr. Labouchere from Mr. T. W. Russell the Parliamentary Secretary to the Local Government Board is of considerable interest. The remuneration of public vaccinators is to be fixed by regulations of the Local Government Board made under Clause 3 of the Bill, and in framing regulations the Board is to take account of domiciliary work. The repeal of Section 6 of the Act of 1867 refers only to the present method of payment of public vaccinators. As Mr. Chaplin has already repeatedly explained, the Bill makes no provision whatever as to the institution of proceedings by vaccination officers and gives no additional powers to the Board in this respect, but powers already exist which the Board now for the first time proposes to bring into operation. Mr. Labouchere is to be thanked for having elicited this clear and definite pronouncement by Mr. Russell:—

Local Government Board, Whitehall, S.W.,
20th May, 1898.

Dear Labouchere,—The reply to your letter of the 18th inst. as to the Vaccination Bill is as follows:

1. The officers appointed under the Vaccination Acts to prosecute persons charged with offences against those Acts or otherwise to enforce those provisions are the vaccination officers.

The Vaccination Bill now before Parliament gives no additional powers to the Local Government Board with regard to these officers or the institution of proceedings by them.

2. The Bill gives no additional powers to the Local Government Board with regard to obliging boards of guardians to institute proceedings under the Vaccination Acts.

3. The substitution of domiciliary vaccination for stational vaccination will render it necessary for the Board to make regulations with regard to the duties and remuneration of the public vaccinators, and the reference to public vaccinators in Clause 3 is for this purpose.

4. The provisions of section 6 of the Vaccination Act of 1867 which are proposed to be repealed refer only to the remuneration of the public vaccinators and in no way affect the remuneration of the vaccination officers or any payments in respect of the institution of proceedings by the guardians of those officers.

Any provision which may be made by the Local Government Board in regulations issued by them as to the institution of proceedings either by the guardians or the vaccination officers would be made under powers which the Board already possess and not under any powers conferred by the Bill.—Yours very truly, T. W. RUSSELL.

THE SUTURE OF THE BILE-DUCTS

IN the *Bulletin* of the Johns Hopkins Hospital, April, 1898, Professor W. S. Halsted describes an ingenious device to facilitate suture of the bile-ducts. He states that to close an incision in the normal ductus communis choledochus has been considered so impracticable, not to say impossible, and the result of suture even of the abnormally thickened duct so uncertain, that it is the practice of all surgeons to wait weeks, months, or even years for the duct to dilate and thicken rather than interfere promptly in cases of obstruction of the common bile-duct by calculus. The operation may be postponed to "give nature a chance" to expel the stone but never for the sake of giving the duct time to thicken. The dangers of this practice are many, and when at last the surgeon interferes the patient is very weak. By using little hammers which he has devised Professor Halsted has sutured the common duct in dogs five times, and the common duct twice and the cystic duct once in man. The wall of the duct is clearly exposed and two presection stitches are inserted to act as retractors. The incision is made between them. The stone having been removed the threads are drawn apart and a hammer of the proper size is introduced. The duct is gently raised from its bed and drawn by the hammer towards the operator. Mattress stitches of silk are then applied, one over the heel and the others in front of the handle. Although the finest stitches are used they necessarily perforate the wall of the duct, but no harm results for the duct is usually sterile.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual general meeting of this society was held on May 20th at 11, Chandos-street, W., Mr. Christopher Heath, Vice-President, being in the chair. From the report read by the secretary it appeared that 8 new members had been elected in 1897, 12 had died, and 1 ceased to be a member, leaving 287 on the books; 1 widow and 3 orphans had been taken on, 4 widows had died, and 2 orphans had become ineligible through age for further grants. At the end of the year there were 50 widows and 12 orphans in receipt of grants. The interest from the funded property had been £2989 1*s.* 7*d.*, the subscriptions were £302 8*s.*, and the donations £22 1*s.* No legacies had been received and a sum of £77 14*s.* life subscriptions had to be invested. The funded property amounted to £97,300. A sum of £2924 16*s.*, including a Christmas present of £434, had been given to widows and orphans and the expenses of the year were £245 7*s.* Mr. Warrington Haward was elected a treasurer in the place of Sir Richard Quain, Bart., deceased; and Mr. C. F. Keele, Dr. Bate, Sir A. Garrod, Mr. Hazel, Mr. Lynch, and Dr. Cullingworth were elected directors in the place of the six senior directors who retire. A discussion took place as to the best way of making the society better known and of increasing the number of members, the society holding out such easy means of providing for widows and orphans of deceased members. A special grant of £26 was made to a widow who was not eligible under the by-laws for ordinary grants. Mr. Heath proposed from the chair a resolution expressing regret that the President, Sir James Paget, Bart., had been prevented from presiding at the meeting for the first time during his presidency of 14 years. A vote of thanks to the editors of the medical journals for their kind assistance in making

known the work and objects of the society was moved by Sir Samuel Wilks, Bart., seconded by Mr. Lynch, and carried unanimously. A vote of thanks to the chairman closed the meeting.

REPORT OF THE MEDICAL OFFICER OF HEALTH OF THE COLONY OF HONG-KONG.

THE island of Hong-Kong, upon which are situated the city of Victoria and a number of villages, has an area of rather more than 29 square miles. The average monthly temperature throughout 1897 was 71·7° F., the highest recorded temperature being 91·8° in September and the lowest 41 0° in February. The total rainfall for the year was 100·03 in., the wettest months being August with 25·5 in. and June with 23 3 in., while the driest months were December with 0 48 in. and March with 0·81 in. The census taken in 1897 showed the total population to be 246,880, classified as follows: Chinese civilians, 233,280; non-Chinese civilians, 8482; army and navy, 5118. Dr. Francis W. Clark states that 4688 deaths were registered during 1897. The deaths among the Chinese were 4484, corresponding to a death-rate of 19 08 per 1000, whilst those among the non-Chinese community were 204, giving a death-rate of 14·89 per 1000. The total number of cases of infectious disease reported by registered medical practitioners during the year was 389, distributed as follows: bubonic fever, 21; small-pox, 293; enteric fever, 65; diphtheria, 2; puerperal fever, 7; and scarlet fever, 1. Among the Chinese 712 deaths from malarial diseases and 173 from beri-beri were recorded. Among the European civil community the largest number of deaths under any one heading were 11 attributed to apoplexy and heat apoplexy; next after these were small-pox and phthisis, 9 each; there were also 4 due to sprue and 1 to beri-beri. Only 21 cases of bubonic fever were discovered during the year, all of them being of Chinese nationality. Dr. Clark does not consider that infection is contracted in the great majority of cases by inoculation through small abrasions of the skin. There were 65 cases of enteric fever reported during the year, 51 being Europeans and 7 Chinese.

WE understand that the Secretary of State has appointed the following committee to inquire into the question of prison dietaries: the Right Hon. J. L. Wharton, M.P., Chairman; A. H. Downes, M.D. Aberd., Medical Inspector, Local Government Board; Herbert Smalley, M.D. Durh., Medical Inspector, Prisons Board; with Dr. John Baker as Secretary.

DR. SIDNEY MARTIN, F.R.S., will deliver the Croonian Lectures on the Chemical Products of Pathogenic Bacteria considered with special reference to Enteric Fever at the Royal College of Physicians of London on the following Tuesdays and Thursdays, at 5 P.M.—June 14th, 16th, 21st, and 23rd.

ON Tuesday last the selection of a Fellow of the Senate of the University of London by the Members of Convocation (to fill the vacancy caused by the death of Sir Richard Quain) resulted in Mr. Fletcher Moulton, M.A., Q.C., heading the poll by more than two hundred votes.

MR. CHARLES SISSMORE TOMES, F.R.C.S. Eng., F.R.S., L.D.S., has been nominated a Crown Member of the General Council of Medical Education and Registration of the United Kingdom in the vacancy created by the death of the late President, Sir Richard Quain.

THE Colonial Office has received a telegram reporting that during the week ending May 21st there were 112 cases of plague in Hong-Kong and 107 deaths resulting from the plague. These figures show some decrease in the ravages of the disease.

THE Lord Mayor's dinner in support of the London Hospital last week resulted in the collection of £75,000, with annual donations of over £4000.

PROFESSOR MICHAEL FOSTER will preside over the meetings of Council of the British Association to be held next year at Dover.

THE BRITISH PHARMACOPŒIA.

IV.[1]

Araroba.—The first substance upon the list of Additions, or "articles included in the British Pharmacopœia, 1898, which were not in that of 1885 or in the 'Additions' of 1890," is araroba. The history of this change is interesting. When this substance was first made official in 1885 a double blunder was committed. It was introduced into the British Pharmacopœia under the name "chrysarobin," with "araroba" and "Goa powder" as synonyms, and it was stated to be the medullary matter of the stem and branches dried and powdered. (In a reprint an *attempt* was made to correct these errors.) Since then much confusion has existed about this drug. The British Pharmacopœial error consisted in making the crude drug official instead of its purified extract and in stating that it was the medullary matter when it was known to be, as now stated, "a substance found in cavities in the trunk." By introducing the crude drug under Araroba and its purified extract under Chrysarobin both mistakes are corrected and it is to be hoped that confusion will cease. Physicians are still in the habit of prescribing this substance—chrysarobin—under the name of "chrysophanic acid." This is a distinct mistake; it contains this acid, it is true, in varying proportion, but the name "chrysophanic acid" should not be used as a synonym for chrysarobin, much less for araroba or Goa powder.

It will be noted that the dose of chrysarobin is omitted. This reminds us of another serious mistake in the last revision (in 1885): in the draft issue of the British Pharmacopœia the dose was given as up to 2 gr.; this was fortunately corrected before the work was published and the dose appeared as ⅛ to ½ gr. This maximum dose was dangerous, as serious symptoms have been noticed after doses as small as ¼ gr., and it has been a wise decision to omit the dose of the drug altogether till a pure chrysophanic acid is made official in a future issue and then its dose will probably be about $\frac{1}{10}$ gr. If practitioners had prescribed this remedy in the official doses many deaths would have been recorded.

Aurantii Cortex Recens is now introduced to make the tincture (1 in 4) which was formerly prepared of the strength of 6 oz. to 1 pint. It will be noticed that the old tincture made from the *dried* peel is now no longer official.

Benzol.—This introduction is of little interest to the practitioner. It was formerly in the Appendix and is now made official simply as a solvent for indiarubber and for use in the making of mustard leaves. It may enter into other preparations which we did not notice, for it should be mentioned that in order to find out for what purposes it was made official we had to search the entire volume from cover to cover as the elaborate index is of no use whatever for this purpose, and it took some hours to find out that the drug was apparently introduced only for the above-named preparations.

Bismuthi Salicylas.—This is a valuable addition; it is called also in the British Pharmacopœia the "oxysalicylate," though it is better known as the basic salicylate. It is a white powder which should contain no free salicylic acid. It is insoluble in water and may be taken for long periods in doses up to 20 gr. without producing any untoward symptoms. It may be sprinkled over wounds as a substitute for iodoform,

[1] Articles I., II., and III. were published in THE LANCET of April 16th and 23rd and May 7th, 1898, respectively.

and it makes a very effective application to sluggish ulcers and is the best salt of bismuth for ulcer of the stomach and diarrhœa caused by fermentation of the contents of the intestinal canal. It has been given with advantage in typhoid fever.

Caffeinæ Citras Effervescens is a granular effervescing powder which contains 1 part of caffeine citrate in 25. Its dose is 60 to 120 gr. which are equivalent to about from 2 to 5 gr. of the caffeine salt. It will be a valuable remedy in migraine and the addition of 5 gr. of antipyrin to each dose should afford one of the most effective and palatable combinations for the treatment of this disorder.

Caoutchouc is only introduced as a means of affording an agent to take the place of the old traumaticine which was represented by the solution of guttapercha which is now no longer official. It may be employed as a means of applying chrysarobin in psoriasis, but a better plan is to make the drug into a paste, to spread it over the spots, and to cover with a piece of Mead's rubber plaster.

Carbon Bisulphidum is introduced as a solvent for caoutchouc and phosphorus and it is probable that the revisers made it official for this purpose only, as no dose is mentioned. It is a powerful agent and notwithstanding its objectionable odour it may be used as an intestinal antiseptic in typhoid fever and tuberculous ulceration in doses of from 1 to 2 oz. of a saturated solution in peppermint water. Its spray will freeze like that of ether and when inhaled it produces general anæsthesia like chloroform. 4 minims to 20 oz. of water make a powerful antiseptic liquid suitable for wounds and ulcers. It has been highly recommended as a substitute for the rectal treatment of tuberculous diseases by sulphuretted hydrogen.

Cocaina.—The introduction of the pure alkaloid will supply a want which the hydrochloride was unable to fill. It is almost insoluble in water and glycerin but it is soluble in 12 parts of olive oil and it can thus be prescribed in 5 per cent. solution in this oil for the relief of ear troubles. The hydrochloride is wholly insoluble in oil. It should be observed that there is now an ointment of cocaine 1 in 25, made by dissolving the pure alkaloid in oleic acid and adding lard. This is a most valuable Galenical preparation. The pure alkaloid should be selected when the practitioner prescribes cocaine in the form of suppository with cacao butter.

Codeinæ Phosphas.—This salt of codeine is introduced chiefly because of its solubility being greater than that of the pure alkaloid which is still official. Its dose is the same as that of codeine which could have been omitted with advantage. It enters into the new Galenical preparation, Syrupus codeinæ, which contains ¼ gr. of the phosphate in a teaspoonful and the dose of which is given as from ½ to 2 drachms. It is a valuable sedative in the hacking cough of early phthisis.

Hydrargyri Oleas is introduced to take the place of the old oleatum hydrargyri prepared by triturating 1 oz. yellow oxide of mercury with 9 oz. oleic acid, which was a most unsatisfactory preparation. The new mercuric oleate is a *precipitated* oleate formed by the interaction of corrosive sublimate and sodium oleate. It enters into a new unguentum—Hydrargyri Oleatis (1 in 4)—which will prove useful in the treatment of joint troubles and enlarged glands but which can never take the place of the simple mercurial ointment in the treament of syphilis by inunctions. It is greatly to be regretted that the revisers did not reduce the strength of the latter ointment to 1 in 3. As it is it is wholly unsuitable for inunction and must always be prescribed in reduced strength. The German Pharmacopœial strength is universally accepted as correct and it is regrettable to see practitioners in this country prescribing "Ungt. Hydrarg. Germ."

Hyoscinæ Hydrobromidum.—The introduction of this substance and its ally—hyoscyamine—marks one of the most noteworthy additions in the new volume. It is also known officially by the synonym scopolamine hydrobromide and is defined to be "the hydrobromide of an alkaloid contained in hyoscyamus leaves, different species of scopola, and possibly other solanaceous plants."

There are still many points to be cleared up about the constitution, dose, and action of the hyoscyamus and belladonna alkaloids, but the revisers were wise in including these two new substances without waiting for further light. The hydrobromide of hyoscine or scopolamine is a powerful hypnotic especially indicated in mania and delirium tremens. Krauss states that "after its administration the maniac collapses as if struck by lightning." It affects the general paralytic differently, his calming down being gradual but also complete. We have seen great benefit from this drug in the insomnia accompanying paralysis agitans. The practitioner should be cautious about the dose; the Pharmacopœia gives it as from $\frac{1}{300}$ to $\frac{1}{100}$ gr., and this dosage is as correct as could be given provided it be understood that the dose is to be administered by the mouth. It is, however, given most frequently (and certainly it is more efficacious when so given) hypodermically, and Binz states that the hypodermic dose should for the first time not exceed $\frac{1}{300}$ gr. This is too small a quantity and the physician may safely administer $\frac{1}{100}$ gr. by the skin. This may be increased to $\frac{1}{50}$ gr. afterwards if found necessary.

Hyoscyaminæ Sulphas is closely allied in its action to the preceding substance. The British Pharmacopœia defines it to be "the sulphate of an alkaloid contained in hyoscyamus leaves and possibly other solanaceous plants." Its dose is given as identical with scopolamine hydrobromide and at first not more than $\frac{1}{100}$ gr. should be given by the hypodermic method. In its action it more nearly resembles atropine than its ally does and it has often been found to fail in insomnia in the ordinary dose. It appears liable to cause delirious excitement sometimes when given with the view of causing sleep. Ringer failed to see any difference between its action and that of atropine in acute mania, but it is just possible that he experimented with an impure salt, as until recently it was very difficult to obtain these alkaloidal preparations in a perfectly pure state. It is used as a remedy for sea-sickness and should be given in doses of $\frac{1}{100}$ gr. by the mouth so as to affect the vision before going on board the ship. It has been used in ophthalmic practice instead of atropine and has been prescribed in paralysis agitans, asthma, chorea, and many other spasmodic affections.

Kaolin is a soft, whitish, insoluble powder, being a purified native aluminium silicate freed from gritty particles by elutriation. It is introduced into the British Pharmacopœia—we found after a prolonged search—as an excipient for phosphorus pill. It makes a good excipient also for permanganate of potassium and gold and silver salts when mixed with a trace of vaseline. Its action as an excipient depends upon its absolute inertness and stability. When carefully powdered it is a very valuable emollient and may be dusted over acute eczema and intertrigo in the same way as fuller's earth and zinc oxide. It will thus be seen that it can well take the place left vacant by the omission of calamina.

Lithii Citras Effervescens is a granular white powder containing 1 gr. of citrate of lithium in 20 gr. It is given in doses of from 60 gr. to 120 gr., equivalent to from 3 gr. to 6 gr. of the citrate. This preparation now takes the place of the old lithia effervescing water or liquor.

Morphinæ Tartras and its liquor are now official for the first time, but their introduction is only of pharmaceutical interest as the salt in no way differs therapeutically from the hydrochloride and acetate. It is more stable and dissolves in 11 parts of cold water and is given in the same dose. It is, however, much more suitable for hypodermic injection and the revisers are to be thanked for the removal of one of the most dangerous preparations included in the 1885 British Pharmacopœia; this was the hypodermic injection liquid which contained 1 gr. of acetate of morphia in 10 minims. Each drop contained $\frac{1}{10}$ gr. and the physician was always liable to give ½ gr. more or less than he intended owing to the imperfections in his syringe and to the concentration of the solution. It is now somewhat less than half the old strength and is made with the tartrate of morphia and distilled water 5 gr. in 110 minims and the dose is from 2 to 5 minims.

Naphthol.—This is beta-naphthol in white crystalline scales or in powder. It is a valuable intestinal disinfectant and has been used in pyloric obstruction, tuberculous ulceration of the bowels, and typhoid fever. Its dose is from 3 to 10 gr. which should be given in cachets owing to its disagreeable sharp taste and unpleasant odour. It is a powerful germicide and it has been used externally for itch and ringworm in the form of an ointment (20 per cent.). It can be used in psoriasis, eczema, &c., as a substitute for tar. When introduced first into use it was vaunted as being absolutely free from toxic properties in enormous doses, but it has been known when recklessly employed to cause a fatal irritation or inflammation of the kidney.

Oleum Pini.—This is the colourless aromatic oil distilled from the fresh leaves of Pinus pumilio—a little pine which

grows over the Alpine regions not far from the snow-line. The oil has been in use under different fanciful names at various continental health resorts frequented by phthisical patients and at home attempts have been made to keep the subjects of pulmonary disease surrounded by an atmosphere saturated with the vapour of the oil. It can be administered internally in doses of from 5 to 10 minims, though the British Pharmacopœia gives no dose, and it can be rubbed into the skin or poured upon the cotton-wool of a mask inhaler. It is certainly of more value than the oil of Scotch fir which is now omitted.

Oleum Rosæ is fragrant otto of rose distilled from the fresh flowers of Rosa Damascena. It is of course only introduced for its odour and it enters into the new official representative of "cold cream"—viz., Unguentum Aquæ Rosæ.

Paraffinum Liquidum.—This is not to be confused with the ordinary petroleum oil used for illumination purposes. It is a clear, oily liquid which is devoid of *colour*, *taste*, and *smell*, and which is not fluorescent. It is obtained from petroleum after the volatile products have been removed by distillation. We have failed to notice any preparation in the British Pharmacopœia into which it enters, though we have carefully looked through the volume, and as no dose is given we are at a loss to account for its presence. It is, however, a demulcent and it forms the basis of several popular cough remedies. It may be used as a basis for hypodermic injections and a vehicle for substances used in the atomiser or sprayed into the larynx. Its boasted nutritive properties, which have brought it into competition with cod-liver oil, are illusory.

Physostigminæ Sulphas.—This salt simply takes the place of the alkaloid physostigmine, which was formerly official but which is now omitted. The sulphate is more soluble and better suited for ophthalmic work, being easily dissolved by the lacrymal secretion.

Picis Carbonis Præparata is prepared coal-tar made by heating commercial coal-tar. Wood-tar is still official, but the introduction of coal-tar is a distinct advantage. Its chief use is in therapeutics of the skin, and its liquor—liquor picis carbonis—is now one of the most valuable preparations in the British Pharmacopœia. There is no agent so useful to the physician in eczema as this liquid made into an ointment, 1 dr. to 1 oz. lard. Equal parts of lanoline and vaseline make a better base for it in most cases.

Pruni Virginianæ Cortex.—Virginian prune bark, with its tincture 1 in 5 and its syrup 1 in 7, is now for the first time officially recognised and it is doubtful if the drug will prove equal to the occasion. We do not say that it is of little or no value, but we think of all the new additions it is the one of least worth. It is a gastric tonic with an agreeable taste and the small amounts of prussic acid present in the preparations add to their soothing properties. The syrup makes a very agreeable adjuvant for cough medicines in phthisis and the tincture was believed by Dr. Allbutt to relieve cardiac palpitation.

Quillaiæ Cortex.—This is an active drug owing to the large amount of saponin contained in it. It contains about five times the amount of this active glucoside that is found in senega. It is therefore a more powerful expectorant and its tincture (1 in 20) should only be given in doses of from ½ to 1 dr. This is exactly the same dose as for tincture of senega, which is made four times stronger, being 1 in 5. Quillaia, or "soap bark" as it is sometimes called, has the power of emulsifying oils and fats.

Quininæ Hydrochloridum Acidum.—This is a very important addition to the British Pharmacopœia. We do not approve of the multiplication of the salts of alkaloids, but this one was needed and the profession will hail its introduction without a murmur of dissent. It is introduced for its great solubility and it dissolves easily in less than its own weight of water. The neutral sulphate requires 800 times its weight of water for its solution. The ordinary hydrochloride is still official; it is soluble in 35 parts of water. It will be seen how valuable is the new salt for hypodermic injection and every other use where great solubility is necessary. Its action and dose are similar to that of the older salts.

Salol, or Phenyl Salicylate, in constant use for several years, now finds its place in the new Pharmacopœia. It is a valuable intestinal disinfectant and its value depends entirely upon the fact that it is not acted upon by acids and therefore passes through the stomach unchanged. Upon reaching the alkaline secretions of the duodenum it is changed into salicylic acid and phenol and these exert their valuable antiseptic actions on the bowel. It is quite safe in 10 gr. doses three times a day, but the maximum British Pharmacopœia dose of 15 gr. if given four times a day might produce symptoms of poisoning. Recently it has been discovered by several observers that Salol is liable to form calculi or concretions in the stomach which may pass on down the bowel without change and which may even cause obstruction. This can be avoided if the drug be mixed with any inert or sparingly soluble powder before administration. It has been administered with benefit in all conditions where an intestinal antiseptic is indicated, and as the substances into which it splits are being eliminated by the kidney it acts as a powerful antiseptic upon the bladder and is less liable to irritate than boric acid.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE LANCET of May 14th contained a report of the first part of the twenty-first meeting of the Royal Commissioners. The latter part of the sitting was occupied by the evidence of Mr. Henry George Hills, who appeared on behalf of the Board of Works for the Wandsworth district.

Mr. H. G. HILLS, in the course of his evidence, stated that there was occasionally a deficiency of pressure in the standpipes used for road watering in some parts of the district. This deficiency was most marked at Putney, near Wimbledon Common. The price charged for the water used was considered to be excessive and application for relief was made under the Waterworks Clauses Act. The result was the reduction in the price charged from 9d. to 8½d. per thousand gallons. The deficiency of pressure existed every summer. The board which he represented had taken no legal steps to have the evil remedied. They had written to the Local Government Board but had not complained to the London County Council.

The CHAIRMAN pointed out that powers existed by which the company which supplied the district with water could have been compelled to supply it at a sufficient pressure and in case of default a large money penalty could be exacted. The Board seemed not to have exercised their statutory power.

The views of the Board with regard to the future management of the water supply are given in the following statement:—

1. This Board has always been, and is now, in favour of a water trust being formed for the purpose of purchasing the metropolitan water companies' undertakings and of supplying the metropolis (or the water area included in such companies' powers) with water.
2. This Board was one of the public bodies who promoted in the year 1891 the Bill intituled "A Bill to place the Water Supply of the Metropolis and the Adjoining Districts under the Control of a Public Authority and to make further Provision for such Supply." (Bill 178.)
3. This Board's views on the subject were embodied in a draft Bill prepared by the Executive Committee of the above-mentioned bodies, of which the representative of this Board was a member, but such draft Bill was not adopted as so prepared and the Bill introduced into the House of Commons, though based on the same principle, differed considerably in important details from the views of the Board.
4. In the opinion of this Board the purchase of the water companies' undertakings should be carried out by a board of arbitration containing representatives of the parties chiefly interested and the Board suggested, and is still of opinion, that such board of arbitration should be constituted as follows—viz., the President of the Local Government Board or his nominee, the Governor of the Bank of England or his nominee, 1 person appointed by the Conservators of the River Thames, 3 persons appointed by the water companies, 3 persons appointed by the metropolitan vestries and district boards and the sanitary authorities of the districts outside the metropolis; and that an instruction should be given to the board of arbitration that in settling the purchase of the water companies' undertakings the valuation should be based upon the value of the property to be purchased and not upon the value of the capital stock or shares of the companies.
5. This Board also suggested, and is still of opinion, that the water trust should consist of 30 members constituted as follows—viz., 6 to be elected by the London County Council, 2 to be elected by the Common Council of the City of London, 1 to be elected by the Conservators of the River Thames, 11 to be elected by the metropolitan vestries and district boards and the sanitary authorities of the districts outside the metropolis north of the Thames, and 10 to be elected by the metropolitan vestries and district boards and the sanitary authorities of the districts outside the metropolis south of the Thames.
6. The election of members of the board of arbitration and of the water trust, by the vestries and district boards and sanitary authorities, could be carried out in a manner similar to that provided by 18 & 19 Vict. c. 120. ss. 45, 46, and 47, relating to the election of members of the Metropolitan Board of Works for certain combined parishes and districts therein specified.

7. This Board is not in favour of the management of the water-supply being given to the London County Council, believing that the Council has sufficient work on its hands in carrying out the very extensive and increasing duties which already devolve upon it under the numerous Acts of Parliament relating to the government of the county of London. The control of the water-supply to so large a population and the carrying on of such an immense business as would be formed by the amalgamation of the eight water companies should, in the opinion of the Board, be under a board of management composed of persons who possess special knowledge and experience, and such board should be exclusively occupied in the management of the water-supply. Moreover, the Council does not represent the whole water area.

8. The Board believe that if such a trust as is above suggested were created the water-supply of London would be carried out at less cost than at present; that much waste of water would be avoided; and that many of the anomalies as to the charges for water and other matters which now exist would be abolished.

We print a table which was put in by Mr. Deacon to show concisely the chief facts which he had given in his evidence.

The twenty-second meeting of the Royal Commissioners was held on Monday, May 16th. The first part of the sitting was occupied by hearing the evidence of M. Gaston Cadoux, chief of the Bureau of the Prefecture of the Seine. At the latter part of the sitting Sir A. Binnie gave evidence with regard to the Staines Reservoir Scheme and his evidence was not concluded at the end of the sitting.

IN EXPLANATION OF MR. DEACON'S EVIDENCE AND IN ANSWER TO SIR GEORGE BRUCE'S AND MR. MELLOR'S QUESTIONS THE FOLLOWING FIGURES ARE GIVEN.

—	Average daily supply to London during the year.	Number of consecutive days during which any water would be supplied from the reservoirs.	Average daily supply to London from river and reservoirs during the periods in Col. 2.	Reservoirs in use.				Reservoirs in reserve for cleaning, &c.		Total constructional capacity of reservoirs.	Number of days' storage of total draught upon the constructional capacity.	Cost.	
				Available contents required for storage of water for filtration and supply to London during dry periods and floods.	Constructional capacity allowing for evaporation and bottom impurity.	Number.	Constructional capacity of each.	Number.	Constructional capacity of each.			At £350 per 1,000,000 gallons stored, being estimate under Staines Scheme, 1896 and 1898 (including power). See Q. 8348, present Commission.	Mr. Deacon's estimate (including pumping power).

* First portion of the 300 millions in Col. 1. † Last portion of the 300 millions in Col. 1.

NOTE.—The figures printed in italics in Cols. 3, 4, 5, 6, 7, and 10 are extracted from the statement made on behalf of the whole of the water companies to the Royal Commission in 1893. (See Evidence, Questions 11,333 to 11,335, p. 430), and referred to in the Report of the Commission. The figures were stated to have been calculated on the conditions of flow of the Thames in 1887. (See Evidence, Question 11,261, p. 248.) The figures on the same lines in the remaining columns are calculated from the figures printed in italics and from the daily flow of the Thames at Teddington. The first line of plain figures is based upon the Promoters' scheme under the Acts of 1896 and 1898. The results in this case are not strictly comparable with those for the higher quantities in Col. 1 because the 35 million gallons a day, Col. 1, Line 1, is not the whole of the water being drawn from the Thames, whereas the lower figures in Col. 1 do represent the whole of such water.

NOTE.—In the course of Mr. Deacon's cross-examination at the twenty-first sitting of the Royal Commissioners he stated that the following items of necessary expenditure were not included in his estimate as given above: (1) Parliamentary and legal expenses in carrying out the Welsh scheme; (2) new mains to connect the London reservoirs for Welsh water with the existing reservoirs of the metropolitan water companies; and (3) the salary or fees of the chief engineer employed to supervise the work.

PLAGUE AND SANITATION IN BOMBAY.

WE have received this communication from a well-informed correspondent:—The rapid diminution of mortality from plague which has continued since the hot season set in is attributed by many to the habit of the poorer classes of sleeping out of doors at this time of the year instead of crowding into unventilated rooms, as is the practice in the cool season, where they sleep nearly naked and packed as close as they can lie. In the face of the recent recrudescence in Karachi and the outbreak at Calcutta this hypothesis is untenable. Research must be pursued still further to arrive at the truth. In the breathing time that the reduced mortality affords the schemes for the amelioration of Bombay continue to receive attention. Their great object is to extend the town and reduce the congestion of population which has hitherto stood principally in the way of good sanitary administration. Openings and streets are to be made in the overbuilt parts of the town, reclamations are to increase the habitable area, and improvements in house construction will offer superior domestic conditions to the poorer classes. All this is in the future. In the meantime all the vices of building construction appear to go on unchecked. A handsome block of lofty buildings in Italian style has just been completed in one of the best parts of Bombay. It measures 141 ft. by 55 ft. in plan. It is divided into three rectangular blocks by two gullies 3 ft. wide and about one-third of the windows give upon these gullies into which sullage water will be discharged and refuse will be thrown by domestic servants. Within, each floor has the fewest possible number of partitions; wooden partitions are usually added to accommodate tenants as they arrive. In such a building uniform ventilation is impossible. The mean temperature of Bombay is nearly 80° F., periods of calm are very frequent, and with the present day temperature in the shade ranging about 90° the damp air, unless

agitated with punkahs, becomes most oppressive. In the block of houses above referred to it would be very difficult to isolate a case of contagious disease; if a case occurred it would probably be concealed until the building was to some degree infected. If such disorders in building are tolerated in the best parts of Bombay it is not surprising that they should continue in the worst.

At the present time about 10 per cent. of the houses of Bombay are empty, but this does not in the least affect overcrowding. Recently it was found that the *halalcores* or nightsoilmen of the Health Department had taken in a number of friends and relations to lodge in the houses provided for them by the Municipality, causing overcrowding. An attempt was made by the Health Department to dislodge them, which was promptly followed by threats of a strike among the *halalcores*. The lodgers have not yet been turned out. If this could occur in the Health Department it gives some idea of the difficulty which may be expected to attend any attempt to teach rational habits to people who consider any rent at all to be an infliction that must be reduced by every possible means.

Since the riots the labouring class in Bombay is more truculent than before and less disposed to conform to sanitary regulations. House proprietors have here a freedom from responsibility which accounts for much of the disorder and dirt in the town, but no steps have yet been taken to increase their responsibility. Their combined influence on the municipality is chiefly devoted to protecting their private interests. The people generally will, if left to their own inclinations, return to exactly the same mode of life that they followed previously to the outbreak of plague and having enjoyed an amount of liberty—not to say license—in matters insanitary for many years that would not be tolerated out of India by any good Government they are just in the condition to meet domestic legislation in the worst spirit. We have now to find out in what way the sanitary state of Bombay may be improved among people who, although they are familiar with many of the features of western civilisation, are bitterly opposed to those forms of control which experience has shown to be absolutely necessary for the safety of a large, over-populated tropical city. Just now the fugitives from Calcutta are carrying plague infection to the remotest part of Bengal and during the past week the news arrived from Garshaukar that the people had been burying plague victims within their houses to escape the hated segregation rules.

Bombay, May 6th.

THE BATTLE OF THE CLUBS.[1]

THE COVENTRY PROVIDENT DISPENSARY.

THE annual meeting of those interested in this dispensary was held on April 26th. The secretary read the report and said that they had had a successful year in every way. A legacy of £30 had been received from the estate of a late member. The receipts were £3177 0*s.* 7*d.* and the expenditure was made up of the following items: paid to medical staff, £1872 9*s.* 8*d.*; to honorary fund, £1274 13*s.* 2*d.* The secretary then reminded the members that a memorial had been addressed to the committee last year by the medical staff asking for some alterations in the rules. The committee had carefully considered these demands and at the present meeting some alterations would be proposed. If our readers will refer to THE LANCET of Sept 18th, 1897, they will find these demands set forth in the article on the Battle of the Clubs. Shortly, they were these: (1) a wage limit; (2) the cancelling of the rule requiring the appointment of a new medical officer when the aggregate salaries of the staff should equal an average of £350 respectively; (3) all the members of the staff to sit on the committee instead of only two; and (4) children's subscriptions to be raised. These were all refused except the last. At the meeting upon the proceedings of which we are now commenting alterations were proposed in Rules 1, 13, 22, 30, and 35. In Rule 1 it was proposed to substitute for the word "members" the words "working men." On being asked to define "working men" the chairman said they would give the words a very wide application. No wage limit would be adopted and they had only suggested the alteration because the committee thought it would please the Medical Council. They did not want to restrict the membership in any way. The alteration was adopted. Rule 13, which is the one dealing with the appointment of another medical officer, being number (2) of the demands of the medical staff, was then discussed and the sum of £350 was expunged and £400 substituted. Rule 22, concerning the payments for children, came next. It was altered in the following way: that whereas up to now the rule had been that in a family of more than three children 2*d.* a week had been considered enough for all under twelve years of age, families of children should now pay 1*d.* per week for the first and ½*d.* per week for any others if under twelve. These concessions are something, but we do not think that a provident dispensary where it is not wished to restrict the membership in any way is to be commended. Also, we should like to know of what the items of the "honorary fund" consist. According to the secretary this fund is the one from which all payments other than the salaries of the medical men are made, and it seems to us that as the total receipts are £3177 odd, and that the medical men only receive £1872 odd, and also that members presumably only join the dispensary to get medical advice—i.e., that the medical men are the providers of the sole benefit—therefore the medical men ought to be paid a much larger proportion of the profits; in other words, they are sweated.

We have been enabled to inspect a copy of the memorial addressed by the medical staff to the committee of the dispensary and from this document it is quite obvious that the six medical men who compose the staff are fully aware of the invidious position they occupy. The memorial says: "You will readily understand that we ..... who hold diplomas and degrees in the various colleges and universities of England, Scotland and Ireland, cannot afford to isolate ourselves from our profession and allow ourselves to be pointed at as men who are guilty of unprofessional conduct in holding appointments in an institution which is founded on lines condemned by the heads of our profession. It is this situation which has brought us before you to ask you to give your serious consideration to our requests ..... in the hope that we may be able to work harmoniously with you in the conduct of this institution in the future and with the approval of our profession." The tenour of the answer returned by the dispensary committee can be read above and we can only advise the gentlemen composing the dispensary staff that the sooner they accede to the invitation of the Coventry Public Medical Service and resign their present positions the better it will be for every one concerned.

THE NATIONAL DEPOSIT FRIENDLY SOCIETY.

We have received the May number of the *Magazine* published by this society containing a letter from the Incorporated Medical Practitioners' Association to the society and an answer from the secretary of the society with regard to the question of imposing a wage limit. The secretary denies the need for a wage limit because no one can join the society for medical aid alone but must also subscribe for funeral and sick pay; also because there are no "club doctors," but any medical man may attend a member of the society at his own pleasure if he is willing to accept the scale of fees drawn up by the society. This scale includes attendance, medicine, and certificates. If the medical man and the patient like to come to an arrangement between themselves on another scale they are quite at liberty to do so, but the society provides a means for medical attendance at small rates which we must allow are better than the usual club rates. Although we cannot approve of any society taking upon itself to fix the emoluments of medical men, if medical men like to agree to the society's conditions there is no more to be said.

Dr. Alfred Cox, the secretary of the Gateshead Medical Association, has forwarded us a letter explanatory of the position taken up by that association with regard to the National Deposit Friendly Society. The reasons for the stand made by the Gateshead practitioners will appear in the National Deposit Friendly Society's *Magazine* for June. We are glad to see that the Gateshead practitioners are thoroughly united and earnestly hope that the practitioners of other centres where the club question rages will follow their example.

[1] A reprint of the previous articles on the above subject has been published in book form entitled, "The Battle of the Clubs," and can be obtained from THE LANCET Office, price 1*s.*

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Coventry Urban District.—The water-supply of Coventry has been matter for the special consideration of Dr. Hugh Snell during the past year, and he reports that the water from the deep wells which supply almost the whole of the city has been shown by chemical analysis to have been of exceptional purity; it is, however, very hard. He thinks, too, that from the view-point of risk of pollution it would have been preferable had the Whitley source been situated on the higher side of the city. The water from what is known as the Barley Brook, a small source of supply only, is apparently open to suspicion and its use has been suspended pending a thorough examination of its opportunities of pollution. The growth of certain algæ in the Coventry water has given rise to trouble and objection from time to time. The growth in question takes place in one reservoir only and Dr. Snell is certainly giving sound advice when he recommends that the reservoir in which it occurs should be covered over to exclude the light. The population of Coventry was enumerated by a special census taken in March, 1897, and was found to be 60,991. During the last six years the remarkable prosperity in the trades of the district has resulted in an increase of population by some 8000, and this increase has naturally led to overcrowding and a need for additional accommodation. The isolation hospital of the district is about to be enlarged and a separate small-pox hospital is being erected.

Cardiff Port District.—The value of our port sanitary organisation received apt illustration at Cardiff during 1897. A vessel arrived in the Penarth Dock from Valencia, and on the sanitary inspector boarding her he found one of the crew suffering from a well-marked attack of small-pox, and he forthwith had the case removed to the small-pox hospital. In commending the action of the inspector, Dr. Walford observes that had it not been for the officer's promptitude Penarth might have suffered from an outbreak of variola. This is the more likely inasmuch as the master of the vessel, instead of bringing up outside the harbour, according to the regulations in force, came direct into dock. We are glad to see that he was summoned and convicted. Another vessel from Valencia brought two cases of small-pox, and by the removal of the patients and the revaccination of the remainder of the crew further cases were probably prevented. Large quantities of frozen meat are imported annually into Cardiff and the inspector of nuisances of the urban sanitary authority is informed by the port sanitary inspector of the destination of the cargo, by which means the meat is kept under careful supervision.

The Vital Statistics of the Leeward Islands, St. Kitts and Nevis. — Although these islands are not, perhaps, very familiar to some of our readers their statistics (especially at the present time) are not without interest. St. Kitts has an estimated population of 32,000, Nevis of 13,700, the birth-rate of the former for 1897 being as much as 42 and of the latter 46 per 1000; the percentage of illegitimate births to total births was in St. Kitts 61·32 and in Nevis 53·84. The still-births amounted in the two islands to 4·05 per cent. among the legitimate and 7·20 among the illegitimate births, the chief cause of these still-births being, it appears, the prevalence of syphilis due to the polyandrous and polygamous habits of the black people. The low price of sugar, too, renders the earnings of the men but small and they are thus unable to support their wives or concubines for the necessary period of rest prior to their confinement. As regards vaccination Dr. W. J. Branch, the analyser of the vital statistics of the islands, reports that during 1897 as many as 1445 successful vaccinations were performed; in St. Kitts debtors are authorised to refuse payment to unvaccinated creditors. The general death-rate of St. Kitts for 1897 was 37·3 and that of Nevis 46·1 per 1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6193 births and 3533 deaths were registered during the week ending May 21st. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 18·4 to 16·6 per 1000, further fell last week to 16·4. In London the rate was 15·7 per 1000, while it averaged 16·9 in the thirty-two provincial towns. The lowest rates in these towns were 8·8 in Cardiff, 9·2 in Croydon, 9·8 in West Ham, and 10·7 in Brighton; the highest rates were 22·6 in Liverpool, 23·6 in Newcastle-upon-Tyne, 23·7 in Wolverhampton, and 24·3 in Sutherland. The 3533 deaths included 380 which were referred to the principal zymotic diseases, against 408 and 383 in the two preceding weeks; of these, 126 resulted from measles, 109 from whooping-cough, 50 from diphtheria, 42 from diarrhœa, 38 from scarlet fever, and 15 from "fever" (principally enteric). No death from any of these diseases was recorded last week in Brighton, Portsmouth, or Blackburn; in the other towns they caused the lowest death-rates in Burnley, Huddersfield, and Halifax; and the highest rates in Wolverhampton, Liverpool, Bolton, and Salford. The greatest mortality from measles occurred in London, Cardiff, and Derby; and from whooping-cough in Plymouth, Salford, and Sheffield. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 50 deaths from diphtheria included 31 in London, 3 in Birmingham, and 3 in Leeds. No fatal case of small-pox was registered during the week under notice in any of the thirty-three large towns, and no small-pox patients were under treatment in the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last was 2241, against 2302, 2271, and 2247 at the end of the three preceding weeks; 223 new cases were admitted during the week, against 205, 209 and 229 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 226 and 232 in the two preceding weeks, declined again last week to 177, and were 134 below the corrected average. The causes of 40, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leeds, Bradford, Hull, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Leicester, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the six preceding weeks from 24·2 to 19·8 per 1000, rose again to 19·9 during the week ending May 21st, and exceeded by 3·5 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·2 in Perth and 10·9 in Leith to 21·8 in Glasgow and 22·0 in Paisley. The 599 deaths in these towns included 31 which were referred to whooping-cough, 27 to measles, 22 to diarrhœa, 14 to scarlet fever, 6 to diphtheria and 4 to "fever." In all, 104 deaths resulted from these principal zymotic diseases, against 90 and 83 in the two preceding weeks. These 104 deaths were equal to an annual rate of 3·4 per 1000, which was 1·6 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had declined from 34 to 26 in the three preceding weeks, rose again to 31 last week, and included 22 in Glasgow. The deaths referred to measles, which had been 27 and 32 in the two preceding weeks, declined to 27 last week, of which 15 occurred in Glasgow, 5 in Paisley, 4 in Dundee, and 3 in Edinburgh. The 14 fatal cases of scarlet fever considerably exceeded the number recorded in any recent week, and included 4 in Edinburgh, 4 in Dundee, and 3 in Glasgow. The deaths from diphtheria, which had been 1 and 3 in the two preceding weeks, further rose to 6 last week, of which 3 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 129 and 109 in the two preceding weeks, rose again to 119 last week, but were 16 below the number in the corresponding period of last year. The causes of 34, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 25·4 to 22·5 per 1000, rose again to

24·0 during the week ending May 21st. During the past four weeks the death-rate in the city has averaged 24·1 per 1000, the rate during the same period being 16·4 in London and 18·1 in Edinburgh. The 161 deaths registered in Dublin during the week under notice showed an increase of 10 upon the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 9 and 7 in the two preceding weeks; of these, 4 resulted from "fever," 3 from diarrhœa, 2 from diphtheria, 1 from whooping-cough, and not one either from small-pox, measles, or scarlet fever. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 2·2 in London and 2·1 in Edinburgh. The deaths referred to different forms of "fever," which had been 3 and 2 in the two preceding weeks, rose again to 4 last week. The 2 fatal cases of diphtheria exceeded the number recorded in any recent week, while the mortality from whooping-cough showed a decline. The 161 deaths in Dublin last week included 21 of infants under one year of age and 50 of persons aged upwards of sixty years; the deaths of infants were below those recorded in any recent week, while those of elderly persons showed a further increase. 10 inquest cases and 5 deaths from violence were registered; and 58, or more than a third, of the deaths occurred in public institutions. The causes of 14, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN JAMESON joins at Woolwich for duty and Surgeon-Lieutenants Archer and Gaine are held in readiness for service in Egypt. Surgeon-Major Battersby is placed under orders for service in Egypt and Surgeon-Major Barefoot has assumed Medical Charge of the Station Hospital, Western Heights, Dover. Surgeon-Major Geoghegan and Surgeon-Captain Clapham have been sent from Cairo to the front for duty in the field hospital at Luxor.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Brigade-Surgeon-Lieutenant-Colonel A. M. Branfoot (Madras) are replaced at the disposal of the Military Department. The services of Surgeon-Captain T. Jackson (Bombay) are placed temporarily at the disposal of the Government of Bombay.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain T. Philip, M.B. Aberd., to be Surgeon-Major.

THE MILITIA MEDICAL STAFF CORPS.

The Militia Medical Staff Corps will train this year during July under the command of Surgeon-Lieutenant-Colonel W. Collingridge, M.D. Cantab. The Hants Company will be attached to the Royal Victoria Hospital, Netley; the Surrey Company to the Cambridge Hospital, Aldershot; and the Middlesex Company to the Herbert Hospital, Woolwich. The Eastern Counties, Kent, and Berkshire Companies will be encamped at Aldershot.

VOLUNTEER CORPS.

Rifle: 1st Sutherland (Sutherland Highlanders): John Kay Tomory to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Manchester Regiment: Frederic Hibbert Westmacott to be Surgeon-Lieutenant. 1st Surrey (South London): Surgeon-Captain C. S. Smith to be Surgeon-Major. 2nd (Prince of Wales's) Volunteer Battalion the Devonshire Regiment: Arthur Russell Rendle to be Surgeon-Lieutenant. 1st Volunteer Battalion the Suffolk Regiment: Francis Ward to be Surgeon-Lieutenant. 1st Volunteer Battalion the Northamptonshire Regiment: John Allison to be Surgeon-Lieutenant.

MILITARY SERVICE IN NORTH-WESTERN ALGERIA.

According to an essay by Surgeon-Major P. A. Cassedebat, which obtained honourable mention at the Académie de Médecine and is published in Duplay's Archives for May, 1898, a visitor taking ship for the province of Oran at Port Vendres, Cette, or Marseilles will scarcely find any difference in his surroundings when he arrives at his destination. The sky of Algeria is not more blue than that of South Eastern France, while on either side of the Mediterranean the flora is equally varied and luxuriant. The cliffs, promontories, and bays likewise bear a general resemblance to each other and in both districts a similar style of architecture characterises the massively constructed public buildings and dwelling-houses. The voyager suddenly disembarking at Mers-el-Kebir or Nemours, with their primitive harbours, might readily fancy himself at one or other of the smaller anchorages between Toulon and the Spanish frontier. With regard to climate the parallel is also for the most part maintainable. It is true that on the Oranian littoral the winters are somewhat milder and that the summers are not only longer but considerably hotter, still owing to the night breezes which almost invariably prevail throughout the latter season, rendering refreshing sleep practicable, it is a question whether life is not more enjoyable in this part of Africa than in Southern France. At Tlemcen, an ancient Arab town situated close to the borders of Morocco at an elevation of 2750 feet above sea level and about forty miles from the coast, the climate is said to be not unlike that of Central France. Every winter snow falls in abundance and remains for a long time unmelted. The æstival heat is much less intense than in the lower regions near the sea; cascades of limpid water are to be seen on all sides, the streams which they feed being utilised for irrigation as in Touraine; and throughout the year the fields present a mass of luxuriant verdure most refreshing to gaze upon. And yet in spite of all these natural advantages; in spite of constant and judicious changes of station from coast to upland, and *vice versâ;* in spite of good food, excellent barracks, admirable arrangements for washing and bathing, perfect scavenging and ventilation; and in spite of the fact that the men are specially selected for their good physique, "there is no European army so forcibly affected by death" as the 2nd Regiment of Zouaves. During the fourteen years from 1883 to 1896 the aggregate strength of the corps was 51,972 men and the deaths amounted to 438. According to Surgeon-Major Cassedebat the average annual mortality came to 8·57 per 1000, whereas in the Home Army the deaths fell from 8·15 per 1000 in 1883 to 6·19 per 1000 in 1893. In France the troops benefited by improved sanitation, but notwithstanding similar measures in Oran the Zouave death-rate has not diminished. Surgeon-Major Cassedebat ascribes the unhealthiness of his regiment to four chief causes: 1. Military duty in a hot dusty climate together with aggregation of the soldiers in barrack-rooms where undisturbed rest is difficult if not impossible. 2. A highly insalubrious vicinity, the manners and customs of the Spanish and native inhabitants, which the author vividly describes, being filthy beyond measure. The atmosphere is not only saturated with the vilest odours, but also laden with noxious germs imperceptible to the unaided sense and therefore trebly dangerous. 3. Exposure to sudden changes of temperature which the soldier cannot always guard against by an appropriate alteration of clothing. 4. Malaria. When first the French occupied Oran, a principal station was at Marnia the hottest spot in the whole province, standing in a damp basin and surrounded by marshy ground. So unhealthy was the place that the garrison had to be relieved every second month. Cultivation and drainage have vastly improved matters, but still the poison exacts victims. Out of the 438 deaths in Surgeon-Major Cassedebat's list 21 were due to paludism.

THE CAMPAIGN IN THE SOUDAN.

IT is fairly certain that if any expedition to Khartoum is to be undertaken it should start in July or August and that the business should be done thoroughly. Not only must the defeat of the Khalifa's forces be secured but precautions will also have to be taken against the retreat and escape of any large portion of them in order to prevent the Dervishes from renewing their opposition and fighting at later dates. The Khalifa's army will probably make a stout defence of their stronghold at Khartoum and a larger contingent of British troops will have to be added to the Anglo-Egyptian expeditionary force in the Soudan than is with it at present. The interval between the date of the advance, when the Nile will be available for transport purposes, and the present time will be occupied in making the necessary arrangements. The provision for sick transport and for the hospital and medical requirements of the force will, of course, have to be finally settled before the advance takes place. With the experience which the medical service and its officers have already had there is but little doubt that these provisions

will be very successfully carried out. There is some prevalence of typhoid fever and dysentery among the troops in the Soudan at the present time.

The following extract from a private letter, dated Cairo, May 12th, will be of interest:—"Two convoys of sick from the front have already arrived and the hospital ship *Mena* is expected here to-day with 12 officers and 120 men. ..... The rest of the wounded Egyptian officers and some British invalids leave for Netley by the *Anubis* from Alexandria on the 14th and should get home about the end of the month. From what we hear enteric fever is beginning to make itself felt up at the front, and considering the intense heat (140°) and the age of some of the men I fancy it will kill many more than the Dervishes will. Dysentery is also prevalent. The Royal Engineers have sent up a lot of the latest pattern filters but there was some hitch about their getting up. The ice machines have also been stopped. A great number of officers and men are coming down on leave and, considering there is no earthly chance of the Khalifa doing anything except 'sitting tight' in Omdurman, it would have been, I think, wiser to have brought down the weakly men of the British Brigade, which might easily have been done, instead of letting them bear the terrible heat and utter weariness of two months' inactive life under defective sanitary conditions. All the branches of the service excepting the Army Medical Staff are getting leave of absence till June 30th. The latter are so short-handed that there is little margin either for casualties or leave, and the men down here are working quite as hard as are those at the front—in fact, there is not a single man who could be sent up without letting some one else in for his work. Of course, this is a state of things that ought not to be and one that tells very hardly on the medical staff. I hear there are 16 more A.M.S. officers to come out, as it is pretty certain that two more brigades are to go up. I have just been told on what should be good authority that the Khalifa has 60,000 men in Omdurman and a number of Krupp guns."

THE BIRTHDAY, MASHONALAND, AND NORTH-WEST FRONTIER HONOURS.

The Queen has been graciously pleased to give orders for the following appointments:—To be Ordinary Member of the Second Class or Knight Commander of the Most Distinguished Order of St. Michael and St. George: Surgeon-Lieutenant Rogers, D S O., head of the Egyptian Sanitary Department. To be Ordinary Member of the Third Class or Companion of the Most Distinguished Order: Andrew Milroy Fleming, M.B. Edin., Medical Director of the British South Africa Company and Principal Medical Officer of the British South Africa Police, in recognition of services rendered by him in connexion with operations in Mashonaland last year. To be an Ordinary Member of the Military Division of the Third Class or Companion of the Most Honourable Order of the Bath: Surgeon-Major-General Robert Harvey, D.S.O. To be a Member of the Third Class or Companion of the Most Eminent Order of the Indian Empire: Brigade-Surgeon-Lieutenant-Colonel A. M. Branfoot. To be Ordinary Member of the Military Division of the Second Class, or Knight Commander of the Most Honourable Order of the Bath, in recognition of services during the recent operations on the North-West Frontier of India: Surgeon-Colonel George Thomson, C.B, Indian Medical Service. Also to be Ordinary Members of the Military Division of the Third Class, or Companions of the said Most Honourable Order—viz.: Surgeon-Colonel Edmond Townsend, Army Medical Staff, and Surgeon-Colonel George McBride Davis, D.S.O., Indian Medical Service. To be Companions of the Distinguished Service Order: Brigade-Surgeon-Lieutenant-Colonel Charles Henry Swayne, Army Medical Staff; Surgeon-Major Johnston Shearer, Indian Medical Service; Surgeon-Captain Thomas Herbert John Chapman Goodwin, Army Medical Staff; Surgeon-Captain John Fisher, Indian Medical Service; Surgeon-Captain William Selby, Indian Medical Service; and Surgeon-Lieutenant James Henry Hugo, Indian Medical Service. To be Surgeon-Lieutenant-Colonel: Surgeon-Major Hayward Reader Whitehead, A.M.S. To be Surgeon-Majors: Surgeon-Captain Charles Henry Burtchaell, M.B. Dub., A.M.S., and Surgeon-Captain John Joseph Gerrard, M.B. Dub. To be Brigade-Surgeon-Lieutenant-Colonel: Surgeon-Lieutenant-Colonel Henry Hamilton, M.D. R.U.I., I.M.S. To be Surgeon-Lieutenant-Colonel: Surgeon-Major Thomas Grainger, M.D. R.U.I., I.M.S.

THE SPANISH-AMERICAN WAR.

The hospital ship *Solace* is at Key West awaiting orders from the United States Government. The ship was some time ago ordered to be made ready for service, which was accordingly done, but no official notice has yet been received for her sailing. The *Solace* is stated to be well equipped with all needful appliances, surgical and otherwise, and to have an ample surgical staff. There is at the present moment no really reliable news about the war and what appears one day is contradicted or altered the next. This is attributable to the fact that little or no intelligence is obtainable from the United States Government and quite rightly so under the circumstances. The general belief, nevertheless, is that a big naval engagement cannot be delayed much longer, notwithstanding that the Spanish naval authorities will probably seek to avoid it. Admiral Cervera is alleged to be at Santiago, blockaded by the American fleet. The accounts that have appeared regarding the losses of the Spanish troops in Cuba during the past year are appalling if they are to be believed. In addition to a total of upwards of 32,000 men having died in the Spanish hospitals about 30,000 soldiers are alleged to have been invalided to Spain during the year. The diseases from which the troops in Cuba suffered were chiefly fevers (typhoid, malarial, and yellow fever), dysentery, and small-pox.

BRIGADE-SURGEON-LIEUTENANT-COLONEL FRANKLIN, I.M.S.

If what our Service contemporary the *Army and Navy Gazette* says be correct, this officer may be congratulated on his good fortune in having been appointed surgeon to the Viceroy of India. "For his personal services, of less than five years on the staff, he will have obtained a C.I.E., Q.H.S., a special promotion to surgeon-colonel's rank (seconded, to allow of his remaining Surgeon to His Excellency the Viceroy), and there are rumours of a further rainfall in the shape of a good service pension, also the crowning triumph later on of a K.C.I.E., and the coveted post of Inspector-General of Civil Hospitals in the Punjab." Brigade-Surgeon-Lieutenant-Colonel Franklin has acted as honorary secretary to the Countess of Dufferin's Fund Association. We do not know, of course, whether our contemporary's prophecy regarding this officer's future is founded upon knowledge, but we wonder whether amid the many good medical officers who have done hard and excellent service of late in India there is no other name to be found with at least equal claims to consideration?

ADMIRAL DEWEY.

A correspondent of the *Birmingham Daily Post* calls attention to the fact that Admiral Dewey, of the United States Navy, whose recent naval exploit at Manila involving the destruction of the Spanish fleet at that station is in everyone's recollection, was a patient in 1883 in the Royal Naval Hospital at Malta when Inspector-General of Hospitals Sir J. N. Dick, R.N. (late Director-General of the Naval Medical Department), was at the head of that institution. Admiral Dewey (who was then in command of the United States corvette *Juniata*) was suffering from abscess of the liver from which he made a successful recovery after surgical operation. The correspondent alludes to the pluck and fortitude exhibited by the patient during his severe illness on that occasion.

THE ROYAL MILITARY TOURNAMENT.

In consequence of the funeral of Mr. Gladstone to-day (Saturday) there will be no performance at the Agricultural Hall. The season will, however, be extended till June 4th and tickets issued for Saturday, May 28th, will be available on the 4th prox., when the prizes will be distributed by H.R.H. the Princess Christian.

DEATHS IN THE SERVICES.

Surgeon Opie Smith, late of the 7th Dragoon Guards (of Hereford), at Clifton, on May 13th, aged seventy years.

RHONDDA DISTRICT COUNCIL.—At a meeting of the Rhondda District Council held on May 20th a letter was read from a Newport firm of solicitors claiming £550 damages from the council for having allowed their medical officer of health to visit the slaughter-house of a client at Porth and seize a quantity of meat. The prosecution fell through, hence the claim. The clerk said the claim was an absurd one.

"Audi alteram partem."

"THE DIPLOMA OF THE APOTHECARIES' SOCIETY."

To the Editors of THE LANCET.

SIRS,—The Medical Act of 1886 did not create an inferior order of practitioners, but, on the contrary, compelled all those who applied to be placed on the Medical Register to produce satisfactory evidence of having qualified for the efficient practice of medicine, surgery, and midwifery, and thereby every registered medical practitioner is on an equality in the eye of the law and logically must be a Physician and Surgeon. The ordinary and common-sense definition of a Physician and Surgeon is that person who is qualified by law to prescribe treatment for injuries and diseases, and the Medical Council never having placed any restrictions over the heads of those who hold the diploma of L.S.A., passed under the Act of 1886, from carrying this out to the fullest extent it follows that we are legally and morally qualified to practise our profession as much as anybody with the M.D. Lond. and F.R.C.S. Eng., and this right we cannot be deprived of until the Medical Council repeals its own Acts. We have been examined by distinguished professors of the various London medical schools and hospitals and have been found efficient to practise the three branches of the profession, and if the Medical Council deny us the right of calling ourselves Physicians and Surgeons because through an oversight on their part they forgot to grant us the use of additional letters with the L.S.A. in order to signify that we are fully qualified medical practitioners I demand that they rectify their mistake and allow us to be designated by the letters R.P., R.S., signifying Registered Physician and Registered Surgeon, these letters being, of course, an addition to L.S.A., as no L.S.A. worth his salt would care to part with such a time-honoured and respectable title as L.S.A. London. Mr. Percy Pope scolds the general practitioners for not electing one of themselves as Direct Representative on the Council and he evidently thinks that the one who was elected—viz., Mr. Victor Horsley—has little sympathy for the general practitioner and none whatever for the L.S.A. portion of that community. If this is correct I am sorry that I voted for him. I don't think it probable that a man gifted with such brilliant attainments and liberality of mind as Mr. Victor Horsley intends to single out the holders of the L.S.A. for special venom when he professes to pose as the staunch advocate of the registered medical practitioner as against the unqualified. Everybody on the British Medical Register owes a debt of gratitude to the Society of Apothecaries for the good work accomplished in proportion to its financial power in prosecuting unqualified and illegitimate medical practice, and not so long ago it had the distinction of being the only corporation who defended the dignity and material welfare of the medical profession; and now, forsooth, in return for these creditable services the Medical Council is apparently going to attempt to pour contempt on the holders of its Licence. Why did the Medical Council allure us to become registered and pay 5 guineas for it if they intended afterwards to bully us for calling ourselves what we practically are? It is a pity the Council does not devote its superfluous funds to the suppression of the prescribing chemist, the brazen quack, and the procurer of abortion, who are rampant in our midst, instead of prosecuting Mr. Hunter, a registered medical man. Surely there are enough external foes to combat without destroying one another. I thank Mr. Percy Pope—and all the more heartily as he is not a L.S.A.—for his fair and sympathetic expressions in his letter in THE LANCET of May 7th. I hope Mr. Carter, the representative of the Apothecaries' Society on the Medical Council, will defend the Licentiates from the unjust attack made on them, and I trust he will vigorously urge the necessity of granting us an additional title to L.S.A., describing us by letters as Physician and Surgeon, which we already are for all practical purposes, and then perhaps we shall be free from further vexatious interference of the Medical Council.

I am, Sirs, yours faithfully,
ARTHUR G. BATEMAN LOBY, L.S.A. Lond. (1889).
Fairhoe, Chudleigh, S. Devon.

To the Editors of THE LANCET.

SIRS,—I should really be most obliged if your correspondent, "M.R.C.S., L.R.C.P. Edin.," would explain his letter. I had always imagined that a L.R.C.P. was really and truly a Physician and I cannot for the life of me see why "superior persons" should call him a snob for so-describing himself. After all I suppose that the only reason why one puts a brass plate on one's front-door is that the public may know that a duly qualified practitioner is to be found behind it. The plate certainly ought to describe its owner as accurately as possible. It seems to me that the very great majority of general practitioners have no right (other than one merely academic) to describe themselves as "Surgeons." How many have ever performed one single major operation? The great bulk of our work is medical, obstetric, and gynæcological, and "Physician" seems to me to describe us far more accurately than "Surgeon."

I am, Sirs, yours faithfully,
May 23rd, 1898. G.P. AND PHYSICIAN.

"THE VACCINATION BILL."

To the Editors of THE LANCET.

SIRS,—Your able leading article in THE LANCET of May 21st on the Bill now before Parliament suggests thoughts as to certain ready remedies which might just now be seasonably applied to the case of the contumacious cranks who pose before the public as anti-vaccinationists, without bringing to bear upon them that sort of pressure of the law which has hitherto done little more than convert them into a small army of martyrs. The case for vaccination and revaccination may be considered closed. No right-minded person can possibly any longer doubt the security which they give to all who submit to the simple operation. The evidence for the practice has been accumulating for a century, and the arguments for it become more and more cogent as time goes on. To restate them would consume your valuable space as well as the advocate's time. The question, it seems to me, is "how and by what measures can small-pox be stamped out." Not by fines and imprisonment, not by distraints. These have hitherto done harm to the cause. It is confidently predicted that the muzzle will in no long time completely stamp out rabies in the dog and society will be thereby safeguarded against a horrible malady. There should be no more difficulty in stamping out small-pox than rabies with a variation in the application of the muzzle. To state the case briefly—thus an unvaccinated person is in constant danger of contracting small-pox. To that extent he is a standing menace to the well-being of the people with whom he may come in contact. Does it not follow, then, that the freedom of such a person should be in some way restricted? The Mosaic law would have cast such an one without the camp as unclean. It becomes thus a question whether the right of public assembly should not be denied him—whether, in fact, his movements should not be muzzled.

The education law provides that every child in the land shall be educated; but an unvaccinated child *ipso facto* being deprived of the right of assembly would be thrown back into the clutches of the law which regulates the education of our children, and would be dealt with as a misdemeanant *quâ* the education law. In the second place, the Bill now before the House provides that when the child leaves school it "may" be revaccinated. But it seems that there should be no "may" about it, for revaccination should be made the passport and the very condition of its entry on public employment. Thirdly, it should be *penal* for an employer to engage unvaccinated labour. Four well-defined cicatrices in primary vaccination should be considered sufficient testimony for the child, but in adolescence the revaccinated should be armed with a certificate from a properly qualified man as a guarantee that he may mix with his fellows without endangering the safety of the community. The vaccination "lines" of a child might thus come to be regarded somewhat as in later life

this or her "marriage lines" are considered. Thus beyond dogging through life the footsteps of the unvaccinated with sundry disabilities, no penalties or pains would be necessary.

I am, Sirs, yours faithfully.

South Godstone, Surrey, May 23rd, 1898. F. W. WRIGHT.

"THE MEDICO-LEGAL ASPECT OF CREMATION."

To the Editors of THE LANCET.

SIRS,—Engrossing matters at a distance from home have prevented my seeing the leading article on the above subject in THE LANCET of May 14th till to-day, when it is, of course, too late to offer you any observations on it of a nature to be available for your issue of May 21st. Nor, to say the truth, is it at the present moment very clear to me how, without a greater expenditure of time and energy than have been left to me, I can hope to add anything very material to the three letters which within the last few months I have addressed to the editor of the *Times*. At the same time there is something which I cannot—or rather which I will not—say to the editor of the *Times* which I can and which I will, if you will only give me room for it, say to you. In the whole course of a long life I have held and doubtless shall continue to hold that a public newspaper is not the place in which to discuss matters of a purely professional and technical nature—matters of which neither the editor nor his readers can be competent judges, and whose influence therefore it is only possible to purchase by highly-coloured statements or by arguments which appeal rather to their prejudices than their judgment. For the moment I will say no more.

I am, Sirs, yours faithfully,

F. SEYMOUR HADEN.

Woodcote Manor, Alresford, May 18th, 1898.

BUBONIC PLAGUE AND CATTLE DISEASE.

To the Editors of THE LANCET.

SIRS,—In the following brief statement of facts I should like to call attention to some coincidences which seem to me to show that diseased meat is one of the factors in the dissemination and causation of plague. Previously to the epidemics of plague in Hong-Kong in 1894 and 1896 an outbreak of rinderpest occurred amongst the cattle at the Hong-Kong dairy farm. In like manner this year an outbreak of rinderpest occurred at the dairy farm, following an epidemic of foot-and-mouth disease, which prevailed in November and December last in all the dairy farms of the colony, native and European. In connexion with this see Brigade-Surgeon-Lieutenant-Colonel Weir's report on the epidemic of plague in Bombay, quoted in THE LANCET of Feb. 26th, page 602.

In 1896 an epidemic occurred amongst the pigs which arrived here from Pakhoi. Pork, it should be explained (sun-dried pork), is one of the staple foods of the Chinese. Dr. Wilson and myself examined several pigs that died from the epidemic and the symptoms were almost identical with those of rinderpest in cattle. We obtained a diplococcus from the spleen, mesenteric glands, and blood of these pigs almost identical with the pest bacillus in man. Similarly this year I have found a like bacillus in the nasal mucus, spleen, and mesenteric glands of cattle that were killed on account of rinderpest. Of course, I know that this theory at present is not proven sufficiently, but any facts that present themselves, like these I now adduce, appear to me to bear forcibly on the etiology of this prevalent disease. Next mail I will forward you specimens of the original bacillus obtained from the rinderpest carcasses and cultures to the third generation of this bacillus in agar bouillon.

There are many cases of rinderpest in Canton just now. At a dairy kept in the Shameen (the European settlement of Canton), where there are 32 head of cattle (Alderneys, Guernseys, and half-breeds), an outbreak of rinderpest has occurred within the last two weeks, the result being that up to the present time 13 animals have been attacked and 4 have died.—I am, Sirs, yours faithfully,

J. M. ATKINSON, M.B. Lond., M.R.C.S. Eng.,
Principal Civil Medical Officer and President of the Sanitary Board.

Hong-Kong, April 9th, 1898.

MEDICAL QUALIFICATIONS AND TITLES IN GERMANY.

(FROM OUR BERLIN CORRESPONDENT.)

IN THE LANCET of April 16th, p. 1069, there was an annotation to the effect that after the commencement of next winter session the German Universities would only confer the degree of M.D. on candidates who had already passed the State examination and thereby become legally qualified to practise medicine. As the laws on medical qualification and examination in Germany are quite different from those in England a few particulars on the subject may be of interest to the readers of THE LANCET. In 1867 the various laws and regulations concerning the practice of medicine which were in force in the different States of the then North German Confederation (Prussia, Saxony, &c.) were replaced by a uniform system applicable to the whole Confederation, the provisions of which were included in the *Gewerbe-Ordnung* (trade-law). In 1871, when the German Empire was founded, this law was extended also to the southern States (Bavaria, &c.) and is now an Imperial law for the whole of Germany. Since this time unqualified practice has not been illegal, anybody being at liberty to give medical advice; but in order that the public might be able to distinguish between practitioners who had received a medical education and those who had not the State instituted a system of examinations of its own, the successful candidates at which receive certificates of "approbation," as they are termed, and thereby become legally qualified medical practitioners. Candidates for this certificate must for their ordinary school education spend nine years in a German *gymnasium* and must pass the *Abiturienten-examen* in general science, after which they study medicine for four and a half years at a university. After the end of the curriculum, in the course of which there is a preliminary examination in anatomy, physiology, botany, &c.—the so-called *tentamen physicum*—the candidate may apply for "approbation," and is thereupon examined by the commissioners appointed by the Government. These commissioners, although they hold examinations in university towns, are not necessarily university professors, but may be any other medical men, such as hospital physicians and surgeons, Government medical officers, &c., whom the Government sees fit to appoint for the purpose. They are, in fact, Government officials and in their capacity of examiners they are quite independent of the universities. After the candidate has passed the State examination, a description of which would make the present article unduly long, he receives the certificate of "approbation" from that state of the empire to which the university belongs. This certificate is valid throughout the whole Empire and confers on its owner the title of *praktischer Arzt*, which he makes use of for his visiting-cards, for his door-plate, and when he signs a medical certificate. This title enables him to hold appointments, to enter the services, and to practise wherever he likes. A certificate of "approbation" may be revoked if it has been obtained by fraudulent means, but this is the only ground for withdrawing it, and a medical man retains it during his whole life even though he may be convicted of a crime and punished. There is no statutory limit of age for medical practice in Germany, there is no annual sum to be paid as a licence or tax, and the only formality which a man beginning practice has to attend to is that he must personally call on the medical officer of the district, show him his "approbation," and write his signature, which is then communicated to all the licensed chemists and to the police officials of the district. It is a penal offence for any unauthorised person to use the title of *praktischer Arzt* or any other title or description by which the public may be induced to believe that he is a duly qualified medical man. The courts of law have to decide in each individual case whether a description used by an unqualified person is one by which the public may be deceived, and the police are authorised to remove door-plates which are held to be infringements of the statute. It is, of course, very easy to secure the conviction of unqualified practitioners in cases of gross imposture, but many of these individuals are very ingenious in evading the law. It results thus from the above that unqualified practice is not in itself an offence, but only

unqualified practice under an assumed title. This is a matter of special interest for foreign medical men who would like to practise under their foreign qualification. If they do so they must understand that they are regarded as unqualified and that when their foreign title is similar to a German one they are liable to be punished. Foreigners desiring to become duly qualified in Germany have to pass all the examinations even if they have already studied medicine and taken diplomas at home. This subject was dealt with in THE LANCET of Sept. 5th, 1896, p. 666 (Students' Number). Exemption from the examination is only allowed by law in cases when the Government desires to appoint foreign medical men of scientific renown as university professors, hospital physicians, &c.; but this provision has come into force only in a few cases of professors of foreign nationality—Austrians, Swiss, Dutch, &c.—who obtained their qualifications by a special order of the Federal Council.

Altogether apart from and independent of the State examination the universities have preserved their old-established right of conferring on medical men the degree of M.D. (Doctor of Medicine), but this is a mere academic title and not a legal qualification to practise medicine. The examination for M.D. differs greatly in the various universities according to their respective statutes and by-laws. As a rule a four years' course of study, an oral examination, and a written thesis are required; at some universities a certain number of printed copies of the thesis must be provided at the expense of the candidate. After the examination has been passed a formal, old-fashioned "disputation" is held between the candidate and the "opponents," whom he may choose among his friends, and after the disputation the dean, in full academical costume, hands the diploma to the candidate. This examination is in several universities made so easy that it is little more than a formality. It is a common joke of German students to say that at some universities the degree may be taken while the train is waiting at the railway station. Graduation expenses also vary very much and the poorer students naturally prefer to take their degrees where there is least to pay, for there is no objection to studying at one university and graduating at another. Although the title of M.D. is not necessary for practice the great majority of medical men nevertheless take it and it is indispensable for those who desire to become *privat docenten* at a university. The degree, being quite independent of the State examination, could hitherto be taken either before or after the "approbation," but as was explained in THE LANCET of April 16th this state of things will now come to an end, for the degree will only be given to those who have previously passed the State examination. This reform originated in the fact that in a few instances candidates who had passed the university examination were rejected at the State examination and when they engaged in practice it was very difficult to make out a case for prosecution because they had legally taken their degree and avoided calling themselves *praktischer Arzt*. The public call every medical man a "doctor" even if he has only passed the State examination.

Although it is almost impossible for foreigners to pass the State examination every facility is afforded them for taking the degree of M.D. They are put at an advantage in comparison with Germans as they may begin to study at a university without the certificate of a German *gymnasium*. They are only bound to prove that they are qualified for medical study according to the laws of their respective countries. They can present themselves for the M.D. examination after a much shorter time of study than is required of Germans who intend to pass the State examination and the time spent at foreign universities is counted in a liberal manner. A great number of foreign medical men, especially Americans, take the German M.D. under this condition, a system which is not without drawbacks. For instance, Germans of deficient general education have gone to America and after becoming American citizens have returned to Germany for the purpose of taking the M.D. degree as foreigners and have then entered on practice in America as German medical men. As the public abroad know little about German qualifications this fact has undoubtedly lowered the credit of the German medical profession. The above described reform, however, will not refer to foreigners, as they will in future be entitled to take the degree without having previously passed the State examination. The whole question of practice and of qualification is a rather complicated one. It would certainly be the best plan to confer the title of Doctor *eo ipso* on every duly qualified man, as in Austria, but this reform is not yet in sight, as it would interfere with the ancient privileges of the universities.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Training of Feeble-minded Children.

THE best mode of educating and training feeble-minded children, of enabling them—generally, perhaps, with a little kindly help—to earn their own living, and of saving them from pauperism and crime, is a problem which has long been forcing itself on the attention of the Manchester School Board. So far the board has been collecting information only, but there is some hope of action being taken before long. Miss Dendy, a lady who was previously to the last election a member of the school board, has voluntarily undertaken an enormous amount of labour in order to ascertain the mental condition of such children and the proportion they bear to the whole number. On May 19th she gave an address on the subject of Dull and Defective Children in Elementary Schools and their Treatment, in which she acknowledged the aid she had received from Dr. Ashby and Dr. Shuttleworth. Her inquiries showed that some 500 children in Manchester board schools were unequal, as Dr. Woodcock said, "to the ordinary strain of school life and had not the capacity to be benefited by the ordinary teaching which obtained in the elementary schools." He considered that there were 1000 children who had claims for special help. They are not imbeciles, or idiots, or lunatics, but are more or less feeble in mind, over whom the guardians have no jurisdiction unless they are paupers, and even then they cannot be sent to asylums unless certified as lunatics. If a working-man has a child mentally below the normal standard he cannot get instruction for the same while at home, and the few institutions for such children are far beyond his means. At present Manchester has no provision for such children. As Miss Dendy stated the school boards in London, Leicester, Birmingham, Bradford, Bristol, and Brighton have already provided special classes for such children and it is strange to find that Manchester, which sometimes thinks itself advanced, should lag so far behind. It must not be forgotten that the facts ascertained as to board school children will obtain equally in all probability with those attending voluntary schools, and it will be equally incumbent on those responsible for their management to provide for the training of their feeble-minded children.

The Present Stage of the Sewage Question.

On May 11th the adjourned summons at the instance of the Mersey and Irwell Joint Committee against the Corporation of Manchester for pollution of the River Irwell and the Manchester Ship Canal came on for hearing at the county police-court before Mr. J. M. Yates, Q.C., the stipendiary, and other magistrates. The Corporation applied for an extension of time. The decision was given on the 14th and the application was dismissed with costs. Mr. Yates reviewed the history of Manchester, dealing with its sewage, its unwillingness to purchase the 200 acres of land required by the Local Government Board, and its inability to persuade the Board to alter their views. He concluded by saying: "The bare facts are that the sewage of an ever-increasing population, now amounting to 600,000, is being turned into an almost stationary body of water unpurified; that this has been going on to a greater or lesser degree for at least five years; and that the corporation are no nearer a final settlement of the question than they were in 1893. If the court were still to prolong this period it would, we think, be stultifying itself and the order made by it by consent of the parties in 1896. We therefore unanimously and unhesitatingly refuse the application." On the 17th the stipendiary granted an application for summonses which were made returnable for June 8th. The Rivers Committee on the 16th resolved to recommend the City Council to appeal at the Salford Hundred Quarter Sessions against this decision, and further recommended the Council to call in three experts to give evidence as to the condition of affairs at the Davyhulme Sewage Works—viz., a civil engineer to speak as to the fitness of the land for the construction

thereon of bacterial filters; a chemist to speak as to the nature and quality of Manchester sewage; and a biologist to state his views as to whether the bacteria can live and perform their functions in the city sewage.

Salford and its Sewage.

On May 23rd the Salford Corporation were brought before Judge Parry at the Salford county court for failing to carry out an order of the court made in July last. The corporation then promised to get rid of the accumulation of sludge which had taken place; to borrow £50,000, the estimated cost of the sewage works; and to let all the contracts and to complete the same, none of which things had been done. On July 22nd last his honour gave the corporation eight months in which to let their contracts and that time expired on March 22nd, since which date the corporation had been liable to a fine of £50 per day. The judge made some severe remarks and gave the corporation to understand that though he would then only impose a penalty of two days' fine of £50 each day, if any further laxity were shown he would impose the maximum penalty of £50 each day.

Manchester Volunteer Medical Staff Corps.

A fund is being started on behalf of the Manchester Volunteer Medical Staff Corps to provide a suitable head-quarters and drill-hall, which they have now a chance of building in Chester-road. So far they have been dependent on the generosity of chief officers of various regiments, who have where possible kindly provided them with accommodation. It will, however, be a great advantage to have head-quarters of their own. It is to be hoped that the services of the corps will never be required in actual war, but while the civilised quite as much as the uncivilised nations of the world are in an ominous condition of unrest it is a sensible thing to be prepared for contingencies, and even in times of peace, reviews and manœuvres generally afford opportunities of showing the importance of promptly obtaining medical aid. The sum required is about £5000, a large amount, but the district is wealthy, so a generous response to Surgeon-Captain Coates' appeal may be expected. So far about £116 have been promised, and among the subscribers are the Lord Mayor of Manchester and Sir W. H. Houldsworth, M.P., while seven members of the Volunteer Medical Staff Corps are giving the sum of £77 12*s*.

May 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Medical Appointments.

MR. JOHN KNIGHT, M.B., C.M. Glasg., has been appointed Assistant to the Professor of Forensic Medicine in the University of Glasgow. The position of Additional Examiner in Physics for degrees in Medicine and Science in the University is vacant. The directors of the Glasgow Central Dispensary have elected Mr. J. Lindley Carstairs, M.A., M.B., C.M. Glasg., Physician for Diseases of Women, vice Dr. Archibald Sloan, resigned; they have also agreed to appoint an extra dispensary physician as well as surgeon.

The Medico-Chirurgical Society of Glasgow.

The following gentlemen were elected at the annual general meeting of the society to be the office-bearers for the session 1898–99:—President: Dr. Geo. S. Middleton. Section of Medicine: vice-president, Dr. W. G. Dun; councillors, Dr. John Love and Dr. Barclay Ness; secretary, Dr. Hinshelwood. Section of Surgery: vice-president, Dr. J. Barlow; councillors, Dr. Robert Kennedy and Dr. Henry Rutherford; secretary, Dr. J. H. Nicoll. Section of Pathology: vice-president, Dr. Walker Downie; councillors, Dr. W. R. Jack and Dr. Workman; secretary, Dr. R. M. Buchanan. Section of Obstetrics: vice-president, Dr. George Halket; councillors, Dr. Munro Kerr and Dr. J. K. Kelly; secretary, Dr. Balfour Marshall; treasurer, Mr. Henry E. Clark; general secretary, Dr. Walker K. Hunter.

Glasgow Eastern Medical Society.

The following gentlemen were elected office bearers at the annual general meeting of the society for the session 1898–99:—President: Dr. Malcolm Black. Vice-president: Mr. W. L. Muir. Secretary: Dr. John McDonald, Dennistoun. Treasurer: Dr. William Buchanan. Reporting Secretary: Dr. John Patrick. Seal-keeper: Dr. James Dunlop. Council: Mr. J. R. Buchanan, Dr. Robert Wilson, Dr. David Young, Dr. A. Munro, Dr. John Knight, and Dr. Daniel McNicol.

May 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Public Health Congress in Dublin.

THE Executive Committee met on May 16th at the Offices of Public Health, Dublin, Dr. Grimshaw, C.B., the Registrar-General, being in the chair. Numerous subscriptions were announced, including £50 from the Royal Academy of Medicine and £20 from Messrs. Guinness, Son, and Co. It was stated that Sir H. Cochrane and Sir Christopher Nixon proposed to give garden parties in connexion with the Congress.

Vicegal Entertainment to the Hospital Nurses of Dublin.

Their Excellencies the Lord-Lieutenant and Countess Cadogan gave an entertainment at the Vicegal Lodge on the afternoon of May 19th to the staff nurses of the Dublin hospitals. The lady superintendents and the resident medical officers of the various hospitals were also invited, and had the honour of being specially presented to her Excellency by Sir William Thomson, the President of the Royal College of Surgeons in Ireland, who was one of the guests. The weather was favourable and the garden party and hospitable entertainment by their Excellencies were most thoroughly enjoyed.

The Royal College of Surgeons in Ireland.

The half-yearly examination for the Fellowship came to a conclusion by a conference on May 21st. The number of candidates was unusually large and included a lady graduate in medicine of the University of Calcutta Miss Cohen passed and was entered on the roll as a Fellow of the College, she being the third lady who has received such honour.

The Belfast Royal Hospital.

From the report presented at the quarterly meeting on May 23rd I find that from Feb. 1st until April 30th of this year there were 567 intern and 5907 extern patients. Special reference was made to the loss which the charity has sustained by the death of the Countess of Shaftesbury. To the end of April there was an increase of £113 15*s*. in general subscriptions and £103 0*s* 8*d*. in contributions from the working classes. There is also a slight increase in church collections. The entire receipts for the eight months ending April 30th amounted to £5125 13*s*. 11*d*. and the expenditure to £6321 10*s*. 11*d*., which is a deficiency of £1195 17*s*., and if the deficit of £349 1*s*. 11*d*. carried forward from the previous year's accounts are added to this it will be seen that on April 30th the hospital was in debt to the extent of £1544 18*s*. 11*d*. The general condition as well as the working of the hospital continue satisfactory. Saturday, May 28th, is fixed for the street collections, when it is hoped that there will be a liberal response.

The Summer Medical Session.

The number of students attending the Belfast Royal Hospital this summer session shows an increase of twelve over that of last year. The feeling is growing among the teachers that more work should be done in the summer so as to prevent the present tendency to overload the students with classes during the winter.

Nursing Arrangements in Larne Workhouse.

At a specially summoned meeting of guardians held on May 15th a correspondence was read from the Local Government Board to the effect that they were satisfied that the arrangements made for the nursing of the sick poor in the workhouse were inadequate and unsatisfactory, and they trusted that the guardians of Larne Union would not bring discredit upon their administration by allowing the standard of comfort and treatment in their workhouse to be behind that of other workhouses. A resolution was passed, declining at the present juncture, when Irish local government is under consideration in the British House of Commons, to make any radical changes respecting night nursing arrangements in Larne Workhouse, and more especially as the medical officer had expressed his approval of existing arrangements, and as no guardian or ratepayer has taken exception thereto.

Belfast Branch of the Royal Medical Benevolent Fund.

At the annual meeting held in Belfast on May 19th, when the President, Dr. Whitaker, took the chair, it was reported that of the 175 members of the medical profession in Belfast only 57 were subscribers, to the extent of

£43 6s., and of the 120 country members only 7 were subscribers, the amount being £4 16s. It thus seems that there are 118 practitioners in Belfast and 113 in the adjoining country who give nothing to the society. It is hoped that these facts will cause our brethren to recognise their responsibilities and that they will join the association. The following officers were elected for the year:—President: Dr. Whitaker. Members of Committee: Professor Cuming, Professor Whitla, Professor Byers, Dr. Brice Smyth, Mr. McDonnell, J.P. (Randalstown), Dr. Merrick, Dr. McKeown, Alderman Graham, M.D.R.U.I., Dr. Gibson (Mount Pottinger), Dr. Bolton, J.P. (Bangor), Mr. James Smith, Councillor O'Neill, M.D.R.U.I., Dr. John McCaw, and Mr. J. C. C. Payne, J.P. Secretary and Treasurer: Dr. Richard Purdon. A special vote of thanks was passed to Dr. McCaw for his valuable services as secretary during the past six years.

May 24th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Syphilis of the Stomach.

AT the meeting of the Academy of Medicine held on May 17th M. Dieulafoy discussed the Nosology of Syphilitic Affections of the Stomach. His conclusions may be summed up as follows. Syphilis of the stomach is not so uncommon as is generally supposed. Syphilitic lesions of the stomach can and do take various forms, from hæmorrhagic erosion to a gummatous ulceration. Probably the action of the gastric juice is a factor in continuing the ulcerative process set up by the syphilis. The symptoms of syphilitic ulceration differ in no way from those of simple ulceration, so that the practitioner should always be on his guard and carefully interrogate any patient suffering from gastric ulcer as to the presence or the reverse of a syphilitic history. Treatment should be begun at once, for in this way a patient may often be relieved by medical measures in whom otherwise it would appear necessary to perform a surgical operation.

Craniectomy.

At the same meeting of the Academy M. Chipault communicated his results in twelve cases of craniectomy undertaken for various complaints. Cases of intracranial tumour, whether of the brain or the meninges, the extirpation of which is considered impossible, are much benefited by a simple craniectomy in the neighbourhood of the growth. The dura mater is left untouched but the operation removes the symptoms of cerebral compression. In the case of a growth which it is considered possible to remove everything should be risked to bring this operation to a successful conclusion. In the opinion of M. Chipault lacerations of the brain, digital exploration, or even resection of portions of the brain, always provided strict asepsis be observed, have marvellously little effect upon the functions of that organ. In cases of localised meningitis with cortical adhesions craniectomy has been known to cause the disappearance of epilepsy and even of paralysis. In infantile brain affections, traumatic or not, craniectomy relieves epileptic symptoms but has no effect upon the paralyses.

The Case of M. Heim.

Your readers have been kept well informed as to the various phases of the case of M. Heim, the assistant professor of the Faculty of Medicine, who was accused by the last elected professor, M. Blanchard, of having "annexed" (*accusé de détournement*) various pieces of apparatus belonging to the laboratory. M. Heim was summoned before the superior council of the University and was first of all sentenced to deprivation of office (*retrait d'emploi*). He then appealed to the superior council of public instruction, which after a searching inquiry acquitted him of the charge of "annexation," but agreed that he had committed certain errors during his tenure of the office and reduced the sentence to a provisional suspension for two years. The position taken up by M. Blanchard in this matter has caused great excitement amongst the students, so much so that the Faculty of Medicine determined to pospone M. Blanchard's course of lectures until the excitement had quieted down. Other riotous manifestations occurred at certain public proceedings of the Faculty of Medicine. These were said to have been caused not by real students but by strangers and measures have been taken to prevent the entrance of such in future, so that it is hoped that the excitement will gradually calm down.

The Congress on Tuberculosis.

The Congress for the Study of Tuberculosis, both human and animal, will hold its fourth session in Paris from July 27th to Aug. 2nd, 1898. The questions propounded for discussion are as follows:—1. Sanatoria as a Means of Prophylaxis and Treatment of Tuberculosis, the discussion to be opened by M. Legendre, M. Netter, and M. Thoinot. 2. The Treatment of Tuberculosis by Serums and Antitoxins, to be opened by Professor Landouzy and Professor Maragliano. 3*a*. X Rays in the Diagnosis of Tubercle, to be opened by M. Béclère, M. Claude, and M. Teissier. 3*b*. X Rays in the Treatment of Tuberculosis, Professor Bergonié of Bordeaux and Professor Lortet of Lyons. 4. The Fight against Animal Tuberculosis by Prophylaxis, Professor Bang of Copenhagen. 5. The Fight against Human Tuberculosis by Disinfection of the Places Inhabited by the Tuberculous, M. A. J. Martin. 6. The Spread of Tuberculosis in the Army and its Prophylaxis, Professor Vallin. It is left open to the members of the Congress to choose a certain number of questions other than the preceding, which will take priority in the orders of the day. The committee of organisation desire particularly to draw the attention of members to the following: the symptomatic and prognostic value of tachycardia in pulmonary tuberculosis, spread of tuberculosis by means of milk and the methods by which it may be avoided—in particular, practical methods of sterilising milk, with provisions for their introduction into general use, the various forms of the tubercle bacillus and their practical signification, the diseases of the solids and fluids of the body which provide a soil for the tubercle bacillus.

Hyperchlorhydria.

At the meeting of the Medical Hospitals Society held on April 25th M. Hayem drew the attention of the society to effects produced by prolonged or too frequent use of alkalines. A number of facts have shown him that the use of large doses of bicarbonate of soda continued for some time brings about in certain patients a most acute hyperchlorhydria. Other alkalies, but especially the bicarbonate of soda, appear to act powerfully in producing an oversecretion of hydrochloric acid. Alkalies act rather by absorption than by local effect and as a consequence mineral waters which assist their absorption are more hurtful than the bicarbonate of soda, although the dose of the latter taken by patients is generally very much larger than the amount which they take in mineral waters, though the latter may be taken in great quantity. Hyperchlorhydria appears to be the consequence of the elimination of the alkaline salt rather than the consequence of its direct action on the glandular apparatus. For alkalies to bring about hyperchlorhydria it is necessary that the mucous membrane of the stomach should contain both numerous and active glands and on this account the effect only appears in certain patients. In those patients whose gastric mucous membrane is degenerated or atrophied, and in consequence where the gastric juice is very deficient in digestive power, alkalies, far from producing relief of the chemical tendency to oversecretion of hydrochloric acid, bring about a great deal of depression and dyspepsia. To sum up, the use of alkalies invariably tends to aggravate the original disorder.

May 24th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Pilgrims and Quarantine.

WE are now in the midst of the Bairam holidays during which is celebrated the annual sacrifice of sheep at Mouna, and while I write the pilgrims must be hurrying back to Mecca as fast as they can, filled to the brim with religious fervour and—roasted mutton. A not very successful attempt was made this year to prevent Egyptian pilgrims from joining the Haj. Holy men agreed that the sacred writings prohibited the faithful from running into unnecessary danger such as the plague already reported from Jeddah and the

civil authority, by means of its mudirs and mamours, advised intending pilgrims to postpone their pious intentions till next year. At one time it looked as if the Egyptians would form no part of this year's pilgrimage and the Government naturally thought it could not do better than follow the example of France, who more than once has forbidden the pilgrimage from Tunis and Algiers in times of epidemic disease in the holy places. But religious custom proved too strong; the Khedive is said to have been bombarded with letters and petitions threatening him, his dynasty, and his country with certain ruin if the pilgrimage were interfered with. His Highness and the Ministers were obliged to bow before this outburst and they permitted the annual journey to Mecca, but they decided in March to make the return of the pilgrims much more difficult than usual. As a rule anyone rich or poor is allowed to go without question, but this year every Egyptian has been obliged to promise to remain in the Hedjaz until the complete disappearance of the plague if it should break out there and, moreover, he has had to prove that he has sufficient money for the return journey and for a stay of at least six months in the holy places. The following contract has been signed before the mudir or governor: "I, the undersigned, after having been well warned about the difficulty and risks to which I expose myself by making the pilgrimage this year, and having decided to go in spite of them, do engage to remain in the Hedjaz in case plague breaks out there and not to return to Egypt until the epidemic is all over. I also promise to provide for the expenses of myself and my family during my stay in the Hedjaz." This is certainly a move in the right direction, and we shall see how far it is practicable to carry it out and even to repeat it every year. One does not at first see what is to prevent any man from gambling away, or even being robbed of, his resources at the outset of this journey. It is difficult for the English officials here to counsel the absolute prohibition of pilgrims because of the bad example set by the Indian Government, which is, of course, well known to prominent Mussulmans here. For half a century England has allowed India to breed cholera at her ease and to distribute it at intervals over the European world. It is now logical to suppose that India, unless prevented, will do much the same with the plague. The pilgrimage was allowed this year to start from Karachi because there were at that time no plague patients reported from that port. But plague had only recently infected Karachi and now, when the pilgrims have been allowed to pass through it, we are officially told that the town has been reinfected with plague from Bombay. But what guarantee have we that the new outbreak is not a recrudescence of the Karachi plague lying dormant? Is India doing everything it can to prevent plague being scattered outside Indian territories?

The Health of Mecca.

The usual bulletins arrive from the sanitary officers of Turkey and Egypt and we are told that the general health is excellent. But it is to be hoped that the existence of plague at Jeddah will be enough to ensure the returning pilgrims being declared "infected." It is true that no plague has yet been reported from Mecca, but are there any medical men there competent to recognise sporadic cases? There is a large death return from "old age," "starvation," and, what is more suspicious still, "infectious fever" and "pneumonia." The annual pilgrimage will continue to be a menace to Egypt and to Europe until a railway is constructed from the coast towards Mecca and until well-trained medical inspectors provided with some authority accompany the pilgrims.

Plague at Jeddah.

It is satisfactory to know that there is no increase of general mortality in the town, and the cases of plague are sporadic rather than epidemic. All this is an additional reason for believing that the present plague is a recrudescence of the Jeddah plague of last year. The natives display much ingenuity in hiding their dead, their sick, and especially the clothing of the dead, so that no one can pretend that the official returns comprise all cases. Moreover, the returns themselves require to be carefully studied. In one house there was a death certified as "pneumonia," while closely following on its heels were in the same house 6 deaths from plague, making it fairly evident that the original death was due to the pneumonic form of plague. Epidemiologists are well acquainted with the premonitory diarrhœa of typhoid fever and cholera outbursts and with the sore throats which precede and accompany epidemics of diphtheria and scarlet fever. It may be interesting at this juncture to remember that a year ago during the height of the plague in Bombay 10 cases of pneumonic plague were found in the Jamsetjee Jejeebhoy Hospital there. Yet this was a hospital which did not admit plague patients, and the 10 cases had all found admission as simple pneumonia.

May 19th.

Obituary.

JOHN ALCOCK, M.R.C.S. ENG., L.S.A., J.P.

A GLOOM has been cast over the whole of the potteries district by the very sudden death of Mr. John Alcock of Burslem. He was in his usual health and left home to pay his ordinary visit as surgeon to the Burslem Haywood Hospital on May 7th, when, on returning, he fell suddenly near his own house and expired immediately. His friends were quite aware of the existence of heart mischief of a grave character and he had had previous warnings that the end might come suddenly, but these made his life none the less active, nor did his devotion to his professional and social duties diminish in consequence. He died literally in harness.

Mr. Alcock was the son of Mr. Samuel Alcock, a distinguished potter, who founded the Hill Pottery at Burslem. Born in 1833, he was educated at the Newcastle Grammar School and the City of London School, subsequently matriculating at London University. Commencing life at his father's manufactory, where he acquired business habits which were of much value to him in after years, his tastes were unsuited and, in consequence, he became the articled pupil of Mr. Samuel Mayer Turner of Newcastle-under-Lyme, at that time one of the surgeons to the North Staffordshire Infirmary. In this capacity young Alcock had the opportunity of acquiring that thorough and practical knowledge of surgical work which stood him in such good stead in after life and that experience in minor details which helps so much to develop the highest professional qualities of a man's character. After a very successful career at King's College Hospital Mr. Alcock was made an Associate and qualified in 1857. After holding the post of house surgeon to the North Staffordshire Infirmary he commenced practice in Burslem and in 1865 was elected honorary surgeon to the infirmary. With the utmost assiduity and unfailing conscientiousness he filled this position up to the day of his death. Mr. Alcock was the first honorary surgeon to the Burslem Haywood Hospital, which he was largely instrumental in securing for the town, and was soon afterwards made a governor with the sanction of the Charity Commissioners. In this capacity he lost no opportunity of maintaining the best interests of the profession, whilst he was ever keenly alive to the welfare of the patients. As a surgeon he was accurate in diagnosis and particularly skilful as an operator, while by his kind and sympathetic manner he won the confidence and esteem of his patients. In every benevolent scheme in his own district he took an active part and liberally supported the same. He was principal founder and chairman of the Burslem Nursing Institute and laboured indefatigably to promote its usefulness.

Mr. Alcock was an ardent Churchman and was for many years churchwarden of St. Paul's Church, Burslem. He was a Justice of the Peace for the county of Stafford. For many years he took an active part in the work of the Staffordshire Branch of the British Medical Association, being elected its President in 1890. His life was active, useful, and unostentatious and his loss will be keenly felt. He was laid to rest on May 11th in St. Paul's Churchyard, Burslem.

GEORGE HUNTSMAN SHAW, M.R.C.S. ENG., L.S.A.

THE death of Mr. Shaw of Attercliffe, Sheffield, who recently passed away at his residence, Carlton Hall, near Worksop, is announced. Mr. Shaw received his medical education at St. Bartholomew's Hospital and obtained the qualifications of M.R.C.S. Eng. and L.S.A. in 1864. Most of his life's work was done in Sheffield; he had practised for

many years in Attercliffe, where he made many friends and was generally respected. In 1884 he was appointed surgeon to the Sheffield General (now Royal) Infirmary, ultimately becoming senior surgeon. Mr. Shaw was fifty-six years of age at the time of his death; he leaves a widow and a married daughter.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Lopez Alonso, Professor of Clinical Medicine in the University of Salamanca.—Dr. G. Grube, Professor Emeritus of Clinical Surgery in the University of Kharkoff.—Dr. T. Halbertsma, Professor of Midwifery and Gynæcology in the University of Utrecht.—Dr. Georg Rosenbaum, whose name is known in connexion with researches on Locomotor Ataxy and Friedreich's disease. He was only forty years of age. His death occurred during his return journey from Italy to Berlin.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 24TH.

THE General Council of Medical Education and Registration opened its session to-day in the hall of the Council, Oxford-street, London. Sir WILLIAM TURNER, President of the Council, occupied the chair.

New Member.

The REGISTRAR (Mr. Allen) read the official notification of the appointment of Mr. CHARLES SISSMORE TOMES, F.R.S., F.R.C.S. Eng., L.D.S., for five years as a Crown member in succession to the late Sir Richard Quain.

Mr. TOMES was introduced to the President by Mr. BRYANT.

Sir John Batty Tuke.

The PRESIDENT intimated that Sir John Batty Tuke had written to say that owing to illness he was unable to be present at the beginning of the session but he hoped to join them before the session was at an end.

The President's Address.

The PRESIDENT then delivered his opening address. After announcing that he had received a letter from Miss Quain, in which, writing on behalf of her sisters and herself, she asked the Council to accept a marble bust of her late father in memory of his long association with the Council, he welcomed as a Crown representative for England in Sir Richard Quain's place Mr. Charles Sissmore Tomes, M.A., F.R.S., whom he described as "distinguished in scientific research, an eminent dental practitioner, and a Fellow of the Royal College of Surgeons of England." With regard to the Midwives Registration Bill Sir William Turner said: "The Bill was put down for second reading in the House of Commons on May 11th, but, as was generally anticipated, owing to the pressure of Government business, the second reading did not take place. From the reports in the public prints of an interview granted on May 2nd by the Lord President to a deputation consisting of the supporters of the Bill it would appear that his Grace the Duke of Devonshire intimated to the deputation that, owing to the small probability of the Bill proceeding during the present Session, the deputation should apply itself rather to the consideration of the terms of some future Bill than to the one now before Parliament. Also, that the promoters of the measure should come to a definite understanding with the medical profession, as represented by the General Medical Council, before they introduced a Bill in another Session. He referred to the objections taken by the Council in their observations on the present measure as well as to difficulties which might arise on the part of the Local Government Board, with which body, as well as with the General Medical Council, the Lord President suggested that the promoters of the measure should put themselves into communication. Should, however, the Bill pass its second reading the Lord President thought that the course which the Government would take would materially depend upon whether the promoters of the Bill were prepared to amend it in Committee so as to meet the suggestions of the General Medical Council. The action of the Lord President in this matter will, I am sure, commend itself to the Council." With regard to the action of the Council towards unqualified assistants the President said that numerous letters had been received from employers asking for an interpretation of questions raised by the Council's resolution and from unqualified assistants, some of whom were married men with families who, having been dismissed by their employers in consequence of the Council's resolution, had been deprived of the means of making a livelihood. A number of these assistants had obtained a partial training at medical schools and a few had finished the course but had not completed the final examination. Petitions had been received from a number of registered practitioners pleading for the institution of special examinations for those unqualified assistants who had gone through a complete medical curriculum and are over forty years of age, while a memorial signed by 138 practitioners in Leeds stated that a difficulty was now experienced in obtaining the services of a sufficient number of qualified assistants to replace those who are unqualified.

The President then continued: "Since the Council rose on April 6th I have, as your President, been called on to consider and give an opinion on an important matter, and as my action has been adversely criticised by a member of the Council and a charge of unconstitutional procedure has been brought against me I cannot pass this subject by in silence. It is due to the Council that I should give them a narrative of the facts. On April 7th our Registrar told me that he had been requested by Mr. Horsley to produce for his inspection and examination certain papers belonging to the Council and asked me what reply should be given to the request. The point was, as far as my experience went, a novel one, but after giving it consideration I instructed the Registrar to tell Mr. Horsley that, in my opinion, he would have to move either the Executive Committee or the Council for leave to have the papers placed at his disposal for purposes of examination. As I felt that the question raised was one which, on the one hand, affected the Council's position as regarded its property in its unpublished papers, and on the other the rights of an individual member to make use of that property before leave had first been granted by a proper authority and before any statement had been made to the Council of the object for which they were desired, I thought it necessary to take the opinion of our standing counsel, Mr. Muir Mackenzie, on the matter. I may remind the Council that although the Act of 1858 did not formally incorporate us, yet that by a subsequent Amendment Act passed in 1862 we became a body corporate and were deemed to be and to have been one since the date of our first establishment. Mr. Muir Mackenzie, in reply to my request for his advice on the question raised, intimated to me that I was absolutely correct in the opinion which I had directed Mr. Allen to communicate to Mr. Horsley, inasmuch as it was established law that the papers of a corporate body belonged to the body and not to its individual members. Accordingly, when later in the month of April the Registrar forwarded me a letter received by him, in which Mr. Horsley asked that certain papers which he specified should be produced for his inspection, I instructed Mr. Allen to reply as follows: 'That the Council's papers are the property of the corporate body and not of its individual members, and that the papers referred to cannot be produced for your inspection without leave being first granted by the Council or the Executive Committee. It is necessary therefore that you should move either the Council or the Executive Committee for an order to permit you to examine and to use them.' On April 27th Mr. Horsley wrote to me a letter, which I received on the following day, in which he asked me questions bearing on my right as President to debar him as a member of the Council from inspecting for the purposes of the work of the Council documents which are its property. In reply I repeated the above instructions which I had given to the Registrar regarding the rights of the Council in its own papers and the necessity of individual members first obtaining leave before they could be produced for inspection. I further stated that so important did I regard this question as one of constitutional procedure that as the Council's chief executive officer I considered that I was justified in giving to the Registrar these instructions. I also called Mr. Horsley's attention to the fact that as the Council would meet at an early date he could then make

application and at the same time explain the object which he had in view in requesting the Council's papers to be produced for his inspection. The Council will observe that throughout this correspondence I have consistently acted so as to preserve the rights of the Council as a corporate body in its own property and in my judgment I should have been guilty of a grave dereliction of duty as your President had I done otherwise. It now remains for Mr. Horsley, should he continue in his desire to examine and use the papers for which he applied, to specify to the Council the papers to which he desires access, to move that the necessary leave should be granted to him, and to state the definite object for which the use of the papers is required. It will then be for the Council to decide whether, having regard to the ground on which the application is based, it is one to which it would be right to accede."

Sir William Turner concluded his first presidential address by briefly stating that information had reached Her Majesty's Government that there was no present intention on the part of the Italian Government to modify the laws regarding the practice of foreign physicians; and that the Home Secretary had informed the Executive Committee that as there could be no legislation on the matter of the granting of death certificates by unregistered persons during the present session he was unable to receive a deputation from the Council, although the Minister had expressed the opinion that legislation was desirable.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the President was thanked for his address and requested to allow it to be entered on the minutes.

The late Sir Richard Quain.

The REGISTRAR read the following letter:—

67, Harley-street, W., April 16th, 1898.

DEAR SIR WM. TURNER,—As one of the sons-in-law of the late Sir Richard Quain I am requested by his family to express their deep appreciation and grateful thanks for the kind message of sympathy contained in your letter to Miss Quain of April 7th and in the resolution passed at the meeting of the General Medical Council.

The family also desire to convey to the Council their sincere gratification at the more than kindly terms in which Sir Richard's services on the Council are refered to in the resolution.

Believe me, dear Sir Wm. Turner, yours very faithfully,

Sir Wm. Turner, M.B. G. A. STE. CROIX ROSE.

He also read this letter:—

67, Harley-street, W., April 26th, 1898.

DEAR SIR WILLIAM,—On behalf of my sisters and myself I am writing to you as President to say that we hope the General Medical Council will accept a small token from us all in memory of our father, who was so long associated with, and so deeply interested in, the Council and its work.

We purpose offering you the marble bust of father which was executed by Mr. Brock, R.A., in 1896, and exhibited in last year's Academy and we should be grateful if you could let us know at your convenience, if acceptable, when it should be sent to the office.

Believe me, yours sincerely,

MARY M. QUAIN.

The PRESIDENT said he had hoped that the bust would have arrived by this time. If it had arrived he should have made a motion from the chair on the subject, but in the circumstances he thought it better to defer the motion.

Mr. Gladstone's Death.

The PRESIDENT said that a suggestion had been made to him by some of the members of the Council that they as a public body should join, he thought he might say all the other public bodies in the kingdom in recording their sense of the loss which had befallen the nation through the death of Mr. Gladstone. He proposed to put this from the chair:—

That this Council desires to place upon record its sense of the grievous loss which has befallen the nation by the death of the Right Hon. William Ewart Gladstone, whose interest in the profession of medicine was ever warm and sympathetic, and under whose administration the Medical Act of 1886 was passed into law. The Council further requests the President to transmit to the widow and family of the deceased statesman a suitable expression of the Council's heartfelt participation in the national sorrow.

He should like to state with reference to this motion that he thought the last time he saw Mr. Gladstone was at a dinner given by one of his predecessors, Sir Henry Acland, to the Council. Mr. Gladstone was the honoured guest upon the occasion. His health, naturally, was proposed and in his reply he took for his text the profession of politics and the profession of medicine and he drew a most eloquent comparison between the two, and the conclusion to which he came was this, that the profession of medicine took a higher place than the profession of politics. Now after the expression of Mr. Gladstone's opinion as to the sense which he entertained of their profession they had another reason for sending this expression of sympathy.

The motion was at once agreed to.

The PRESIDENT said it had been pointed out to him that the funeral was to take place on Saturday and the tickets admitting persons to Westminster Abbey were to be given out by the Earl Marshal. If the Council wished it he would write to the Earl Marshal and ask for 30 tickets.

The Council expressed approval of this course.

The Business Committee.

This committee was constituted as follows: Dr. MacAlister (chairman), Mr. Bryant, Sir Philip Smyly, and Dr. Bruce.

Service Examination Results.

The REGISTRAR presented the following tables, viz.:—

(*a*) Table showing Results of Professional Medical Examinations during 1897; (*b*) Table showing Results of Professional Examinations for Qualifications in Sanitary Science, Public Health, or State Medicine during 1897; (*c*) Table showing Results of Professional Dental Examinations during 1897; (*d*) Table showing Results of Preliminary Examinations during 1897; (*e*) Table showing Exceptional Cases in regard to Length of Course of Study during 1897; (*f*) Table showing Results of Competition held on Nov. 22nd, 1897, for Commissions in the Medical Staff of the Royal Navy; (*g*) Table showing Results of Competition held in February, 1898, for Commissions in the Medical Staff of the Army; and (*h*) Table showing Results of Competition held in February, 1898, for Commissions in the Indian Medical Staff.

Dr. HERON WATSON moved that the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy, the Director-General of the Army Medical Department and the Examining Board of the Medical Department of the Indian Medical Service for the information they had furnished. He explained that the Director-General of the Army Medical Department had on this occasion furnished the information the Council desired with regard to defects in spelling and composition.

Sir RICHARD THORNE seconded the motion.

Sir PHILIP SMYLY suggested that the bodies should have some means of testing the accuracy of the information as to defects of education.

Sir DYCE DUCKWORTH said that the candidates themselves were responsible for notifying the particular examination in arts they had passed and surely the candidate himself ought to know the examination.

Dr. BENNETT complained that there was no means afforded of identifying the delinquents.

Dr. REID made a similar complaint.

Sir DYCE DUCKWORTH said that many of the candidates who showed defects in general education went into the service because the examiners could not pluck them, and he thought it only right that without giving the names of the candidates they should point out the bodies through whose portals they had passed.

Sir WILLIAM THOMSON insisted that the bodies ought to have some means of testing the accuracy of the statements made. Licentiates did not like to have a slur cast upon the body whose Licence they held and what they asked was that they should be satisfied that the thing had been done upon reasonable evidence.

Dr. GLOVER said he wished to call attention to the enormous proportion of rejected candidates and he would single out a few instances. In the case of the Examining Board in England by the Royal Colleges of Physicians of London and Surgeons of England he found that in the second examination there were 318 rejected and 342 passed. In the case of the Apothecaries' Society of London in the second examination the rejected were 98 and the passed 88. The University of Cambridge in the first examination had 100 rejected and 116 passed, and in the second examination the rejected were 97 and the passed 87, while in the final examination they had in the first part of it 62 rejected and 45 passed. The Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow in the first examination had rejected 120 candidates and passed 111; in the second examination 158 were rejected and 139 passed; and in the final examinations 261 were rejected and 205 passed. The University of Edinburgh had in the first examination 201 rejected and 227 passed. These figures were to his mind very appalling.

Dr. MACALISTER said that the figures did not quite represent the facts, for in a single year the same man might be rejected several times and he could only be passed once.

Dr. ATTHILL said he thought the tables very creditable to the examiners.

Mr. TEALE thought they showed that their teaching was practically a failure because the more they examined the more they plucked.

After some further discussion the motion was adopted by the Council.

Mr. Horsley and the President.

Mr. HORSLEY asked leave to call the attention of the Council to the infringement of the rights and privileges of the members of the Council by the recent action of the President in compelling the Registrar to refuse a member the exercise of his right of inspection of documents the property of the Council.

Dr. MACALISTER took exception to the word "compelling" in the notice.

The word "directing" was thereupon substituted and the leave craved was given.

Mr. HORSLEY said that the matter which he desired to bring to the notice of the Council had in it novel principles in one sense, but not quite in the sense which the President in his address meant them to have. According to the President's statement it would appear that in all conditions no member of Council, even when seeking to instruct himself in the work of the Council by the study of documents in possession of the officials, had a right to inspect these documents. It had been suggested that no member of Council had taken sufficient trouble to investigate for his own instruction documents which had been obtained at great trouble for the benefit of the Council. He did not know that that was so as regards others, but in his own case it was not so. From November, 1897, until April of this year he had entered the Council's office, requisitioned documents from the Registrar, and received them without the slightest let or hindrance and examined them at his leisure. On April 7th he was refused by the Registrar the privileges that he had been enjoying for the previous months. He was on that day informed by the Registrar that in refusing inspection of the documents asked for he was acting under the President's order. This order he (Mr. Horsley) considered to constitute an encroachment on the rights and privileges of members of corporate bodies such as the General Medical Council and from what had been heard, Mr. Muir Mackenzie's opinion on the subject did not in the least degree alter his views of this matter. It was novel, he thought, for members to learn that they were not to be allowed the privilege of inspecting documents belonging to the Council. The President's direction did seek to deprive them of rights and, moreover, claimed for the office of President a certain power of dictatorship for which he thought neither title nor justification existed. In drawing up his notice he used the word "compelling" because he understood from Mr. Allen that but for the order he would not have given a refusal, but as it was the President's order he had no other course open to him. He did not think the Registrar was legally entitled to give a refusal, but he (Mr. Horsley) accepted the Registrar's statement that the refusal was given in accordance with the President's order. Leaving that matter meantime he would return to the historical. From November till April he was engaged in reading the various counsel's opinions with the view of bringing before the Council the very extraordinary cost of the legal work. He acquired by that research a number of very important facts and when his work was suddenly arrested by the President's order he wrote the following letter:—

25, Cavendish-square, London, W., April 27th, 1893.

DEAR MR PRESIDENT,—

I am informed by the Registrar of the General Medical Council that you have instructed him to refuse me the opportunity of inspecting certain specified documents belonging to the Council and in his custody. Will you kindly inform me:—

1. By what regulation of the Council or legal enactment do you claim the right to debar me, a member of the Council, from inspecting for the purposes of the work of the Council documents which are its property and open to the inspection of the Registrar?

2. Do you claim the right to refuse me access (for the purposes of the work of the Council) to all unpublished documents of the Council as well as to those specified in my application to the Registrar?

3. Do you consider that you yourself are similarly debarred from inspecting the documents of the Council except with the special leave of the Executive Committee or Council, which you assert I must obtain?

Inasmuch as your instructions to the Registrar if correct will preclude any member of the Council from making any adequate inquiry into the destination of the funds of the Council, which are public moneys, the importance of the question of constitutional procedure involved compels me to ask you for the courtesy of a prompt reply.

Yours faithfully,
(Signed) V. HORSLEY.

Sir William Turner, President of the General Medical Council.

He (Mr. Horsley) was sorry to say that he received no specific answer to any of the three questions. To the second he received no reply at all. He therefore concluded that the President's ruling was intended to apply to all documents of all kinds whatsoever. He should like to have some information on the subject now. With regard to the third question, he did think it was very important that the Council should be informed as to whether the President of the Council possessed certain rights and privileges above other members of the Council when the work of the Council was involved. The only reply he received to this question was that his juniority in the Council was probably the reason of his asking such a question. He ventured to hope that the Council would receive a different reply. The first of the three questions involved a matter of principle. The only reply to it that he had received was that which had been given in the President's address—namely, that the documents of the Council were the property of the Council, and for that reason any inspection of them by a member of the Council could only be carried on after leave had been obtained from the Executive Committee or the Council itself. They were all agreed that the documents were the property of the Council, but the members of Council for the time being were part proprietors of them, and as far as inspection went he conceived that they were entitled to inspection of the Council's property. They were co-trustees not only of the work but also of the property of the Council, and as a co-trustee he held that he had a perfect right to inspect the documents belonging to the Council. No evidence or order of Council or legal enactment in support of the President's position had been given him. In fact, he had received no answer to his point at all. He quite agreed with Mr. Muir Mackenzie that it was established law that all the documents of a corporate body were the property of that body, but he took issue with him when he went on to say that the President was quite right in refusing access to the Council's documents. He should like to see the case on which Mr. Muir Mackenzie's opinion was given. He was surprised that Mr. Muir Mackenzie should have given such an opinion. It was totally at variance with the opinion given to the Council in July, 1882, by Mr. Farrer, their solicitor. Therefore he asked them to approach this case from the point of view of common sense, and that the Council should do as other public bodies, and so far as he could learn from inquiries the documents belonging to these were open to the inspection of members. It was not his object to raise discussion and therefore he did not conclude with a motion. His object was to report to the members of the Council as his co-trustees what had happened, and what steps they should take it was for them to decide.

At the request of the PRESIDENT the Registrar read the opinion given by Mr. Muir Mackenzie.

The PRESIDENT considered that the opinion just read supported his action and the answers he gave to Mr. Horsley.

Mr. HORSLEY wished to make some remarks on the opinion.

Dr. MACALISTER took the view that Mr. Horsley should have the courage of his opinion and make a motion.

The PRESIDENT was quite willing that Mr. Horsley should be heard, even though there was no motion before them. He had nothing to hide and so long as he had the honour to sit in that chair he hoped his action would be perfectly open and that he should never do anything of which he would need to be ashamed.

Mr. HORSLEY pointed out that counsel's opinion was not parallel with his position. Independent examination by an individual member was much stronger than he contemplated. He had simply stated that he wanted to see certain documents for the purpose of the work of the Council.

Sir C. NIXON proposed to move that Mr. Horsley should be granted the use of the documents of the Council for the purpose of carrying on an investigation in connexion with the legal expenses of the Council extending over a number of years. He had not the slightest doubt that the President acted to the best of his judgment in the matter and he expressed no judgment as to whether the ruling was right or wrong; but as it had come to the knowledge of the Council that an allegation had been made as to the way in which they conducted their legal affairs it was their duty to have the allegation investigated to the fullest degree. It was for that reason he would urge it upon the Council that they give Mr. Horsley the very fullest facilities for carrying out his investigation. That was a different question from the question as to whether every member had the right to investigate the secret documents of the Council.

The PRESIDENT ruled that this was not the time to receive such a motion as Sir Christopher Nixon had indicated. It was not in order with regard to the manner in which an application for the inspection of documents should be made. Mr. Muir Mackenzie advised that not only should the application be made to the Council, but that the documents asked for should be specifically stated and that the objects for which these documents were required should also be distinctly stated. He should consider himself precluded from putting a motion that did not observe all these points.

Mr. BRUDENELL CARTER thought the only course they should now pursue should be to get Mr. Horsley to move for permission to examine the documents he wished to see. If any such permission were granted it should be in very specific terms.

Dr. MACALISTER contended that there was a preliminary matter to be disposed of first. They ought to declare that their President had fully vindicated his course of action, and to give effect to that view he had to move:—

That the Council, having heard the President's statement as to the legal ground of his action in reference to Mr. Horsley's applications expresses its complete satisfaction therewith and passes to the next business on the programme.

Dr. PETTIGREW formally seconded the motion.

Mr. TEALE, in supporting the motion, pointed out that the methods which had been followed out by Mr. Horsley in connexion with this subject formed a new departure in the proceedings of a member in relation to the Council. He felt that the whole Council had been injured by its adoption and particularly by its being first of all made public through the columns of the medical press. It would lower the character of the Council if they pursued methods of the kind in question.

Mr. HORSLEY said he had responsibility which Mr. Teale as a Crown representative did not have. He had responsibility to those who had sent him to the Council and he should always conceive it to be his duty when the interests of those persons were seriously concerned to report the fact to them.

Dr. GLOVER considered that the only use they could make of the painful discussion which had taken place was to see that another of the kind did not occur. While he gave Mr. Horsley full credit in trying to get the best possible terms for work done for the Council he must point out that there was a right way and a wrong way of raising the question and in his judgment it was not the right way for a member between sessions to make *ex-parte* statements and charges against persons who were not in a position to make answer. If in a general way this was true as regards individual members in their fair stand-up fight as between themselves it was true in a more acute sense as respects members and their dealings with the President, who certainly desired to maintain the dignity and efficiency of the Council. They had elected Sir William Turner to the chair unanimously and he had scarcely taken his seat in it when he was charged with a deliberate attack on the rights of individual members and a new and very serious infringement of constitutional conduct. As a Direct Representative sincerely desirous of meeting the views of the profession he said that he did not see where was the obligation to publish the charge against the President six weeks before the meeting of the Council. They should endeavour to see if they could not conduct charges against each other in such a way as would prevent a recurrence of such a discussion as they were having. So far as the right to use Council documents was involved he would have something to say later if any debate arose, but this was not a question of principles but one of methods. It would be his duty unhesitatingly to support the motion.

Mr. BRUDENELL CARTER said Mr. Horsley in the notice on the programme had entirely failed to draw a very important distinction between opinions—probably erroneous—and fact. He used the word "infringement," but they had it from their legal adviser that there was no infringement. He also referred to members' right to inspection of documents, but that right existed only under specified conditions. He therefore wished to call attention to the lightheartedness with which Mr. Horsley put on the paper statements which according to their legal adviser were not true.

Sir WILLIAM GAIRDNER argued that it would be a mistake if the public formed the impression that Mr. Horsley had been hardly dealt with. It was very important in such a body as theirs that there should be loyalty in connexion with secret documents and he thought that they should not only at once say that they approved of the action which the President had taken in this instance, but should go further and completely and thoroughly relieve the President from the innuendoes contained in Mr. Horsley's statement and in the letter to THE LANCET. He thought it atrocious that the President should be the subject of such insinuations.

Dr. PETTIGREW, as the seconder of the motion, wished in justice to the President to homologate the action which he had taken. Everyone knew that Sir William Turner had the honour of the Council at heart and that he proceeded with the greatest deliberation and caution. He (Dr. Pettigrew) could not see how the President could have acted otherwise, as he had shown nothing but a desire to have everything done orderly. It was a matter of the gravest importance that the President should have their support and sympathy on the present occasion. If this thing were carried against him it would simply mean that they had no confidence in him.

Mr. GEORGE BROWN regretted very much the turn the discussion had taken and that there should have been this personal attack on the President.

Mr. HORSLEY: It is not a personal attack.

Mr. BROWN considered that it bore the appearance and he could not but regret that the discussion had developed the personal tone it had assumed. He did not feel that he could vote against the motion, but he hoped that no obstruction would be placed in the way either of Mr. Horsley or other members of inspecting documents which came into the hands of the Council and which it was thought desirable or necessary to scrutinise.

Dr. MACALISTER pointed out that a member for the first time claimed a legal right and it was necessary that that should be determined. So far as he was concerned he could express complete satisfaction with the legal grounds on which the President had acted.

The motion was then put to the Council and was carried without dissent.

Dr. PETTIGREW asked that the names should be taken.

Sir CHRISTOPHER NIXON appealed to Dr. Pettigrew not to press his request.

Mr. HOBSLEY wanted to know whether it was possible to make a speech when a request of the kind in question was made to the Council.

The PRESIDENT said he thought not.

Dr. LOMBE ATTHILL hoped it would be felt that there was no necessity to call the roll. They all knew that the adoption of the motion was unanimous.

Dr. PETTIGREW: Well, if there is such a strong feeling I will not insist.

The PRESIDENT: Then this closes the matter. The next motion is a very important one, and we may as well have the 4 o'clock cup of tea before proceeding with it.

This was, our reporter states, an unusual course to adopt. It had hitherto been the custom for the Council to adjourn at 4 o'clock on the opening day of each session in order to enable the committees to complete work for subsequent sittings, but on being questioned in regard to this new departure Dr. MACALISTER, the new chairman of the Business Committee, explained that "the next motion" was "all of a piece" with the subject which had been discussed and it ought to be dealt with before the Council adjourned for the day. On the Council's return, and because of its having been carried that they should proceed to the next business, Mr. Horsley went on with a motion of which he had given notice to the effect that there should be an alteration in the conduct of the legal business of the Council.

The Legal Business of the Council.

Mr. HORSLEY moved:—

That a committee be appointed to inquire into, firstly, the conduct of the legal business of the Council in the past and at present, and secondly, the cost to the Council incurred thereby; the committee to report to the Council during the present session.

In supporting this proposal Mr. Horsley said that before he became a Member of the Council he had taken great interest in its legal work, and in an appointment which he held he had become acquainted with a great deal of the detail of the work. On becoming a Member of Council he had applied that knowledge to what he conceived to be the financial position of the Council. It had appeared to him that while their income was decreasing the general expenditure was increasing, and it seemed to him expedient to study the conduct of the Council's legal business to see whether they could not introduce into that certain amendments

and alterations which would secure efficiency on certain points and at the same time economy in expenditure. An investigation into the subject had been carried on in the way he had indicated, and in now asking for the appointment of a special committee he did not know that it was necessary to go into detail. At present the conduct of the legal business of the Council was left very much to the solicitor of the Council, and he had found that that had led to the solicitor's dealing with matters which he (Mr. Horsley) considered came within the professional purview and should be dealt with by the Council as a whole. If that were altered there would be, he conceived, very considerable saving. But behind it there were certain questions relating to the Council's work: first, that portion of the work which might be spoken of as administrative and, secondly, that portion of it which was generally referred to as penal. He admitted that he had no experience in regard to the first, but he claimed that he had had considerable experience in connexion with the penal procedure of the Council, and from that experience he had no hesitation in saying that up till 1897, at any rate, the penal work of the Council had been carried on in a very extravagant way. He had extracted cases from the documents he had seen in which the money, as he thought, had been absolutely wasted. A committee such as he asked for could see whether he was right or not in this and could report to the Council as to what steps could be taken to diminish the expenditure in which their procedure apparently now involved them. He had found that there had been extra expenses incurred in the way of taking counsel's opinion on matters which ought to be decided by professional medical means rather than legal means. In that direction he thought great saving could be effected. He had further found that the Council had been advised to proceed in some particular direction and that some months later they had been told to go in exactly the contrary direction, the expenditure in getting legal advice being thereby wasted. As to the way in which the legal accounts were presented to the Council that was not satisfactory. Details were not given in these where they should be given. Sometimes at the end of an account a lump sum of 100 or 150 guineas appeared in place of a detailed statement. The Council obviously could not control expenditure when the accounts were presented in that way. Again, the accounts were not presented to the Council in time for criticism. They had to be presented to Parliament, and the time at which they had to be submitted to Parliament was a time when the Council could not examine them. It was his view therefore that the financial circumstances of the legal work of the Council had not received examination, and because of that he had put his proposal on the paper with a view to the conduct of the legal work being examined into and its method altered so far as might seem advisable. As to the mode in which the legal business had been conducted, he personally thought that the method had not been so efficient as it should have been, and therefore he should like to lay before a special committee facts pointing in that direction in the hope that these facts would receive investigation.

Dr. GLOVER formally seconded the motion.

Mr. BROWN said that he did not wish to say anything disrespectful of the Council's legal advisers, but he could not help coming to the conclusion that if they had law officers to advise them in some cases the advice would be different from that on which they had now to act. It was because he thought so that he had placed on the paper the following notice of motion:—

That a special committee be appointed to consider and report as to the advisability of appointing special law officers to conduct such prosecutions as may be ordered by the Council to be taken under the Penal Clauses of the Medical Act of 1858.

Mr. HORSLEY said that the subject of this proposed motion was included in his proposal.

Mr. BROWN: It seems to pretty much cover it.

The PRESIDENT: Then you withdraw it?

Mr. BROWN: If it is understood that it is included.

Dr. LOMBE ATTHILL asked Mr. Horsley to depart from the idea that there could be any report from a committee during the present session. The subject was important and it was impossible that any committee could report on it in a few days.

Mr. HORSLEY willingly withdrew the words "during the present session."

Dr. MACALISTER said he should like to know what case there was for a committee on the subject in question. Certainly none had been made out. The Council had two treasurers, a finance committee, and an executive committee, all of whom were bound to inquire into the very question raised by the motion, and he could see no reason why in addition there should be a special committee to make inquiry on the subject.

Dr. GLOVER was of opinion that the very fact of the question having been so sharply raised was a sufficient answer to Dr. MacAlister. He himself was a member of the executive committee but he must admit that the details of the accounts in question had not been adequately brought before the committee. In the circumstances he thought the motion was a reasonable one.
